## ABSTRACT

The first part of this thesis is an analysis of the *virtual large cardinals*, being critical points of set-sized generic elementary embeddings where the target model is a subset of the ground model. We show that virtually measurables are equiconsistent with virtually strongs, and that virtually Woodins are virtually Vopěnka. We separate most of these large cardinals, but show that such separations do not hold within core models. We define *prestrong cardinals*, being an equivalent characterisation of strongs, but which in a virtual setting are strictly weaker than virtually strongs. We show that the existence of this separation is equivalent to the existence of virtually rank-into-rank cardinals in the universe, and that virtually Berkeley cardinals can be characterised in the same fashion with On being virtually *pre-Woodin* but not virtually Woodin, answering a question by Gitman and Hamkins. Building on the work of Wilson, we show that the virtual version of the *Weak Vopěnka Principle* is equivalent to a weakening of virtually pre-Woodins. We end the first part with several indestructibility results, including that a slight strengthening of the virtually supercompacts is always indestructible by  $<\kappa$ -directed closed forcings.

The second part is concerned with connections between the virtual large cardinals and other set-theoretic objects. We analyse cardinals arising from a certain *filter game*, for various lengths of the game. When the games are finite we show that this results in a characterisation of the completely ineffable cardinals, and at length  $\omega$  we arrive at another characterisation of the virtually measurable cardinals. At length  $\omega + 1$  the cardinals become equiconsistent with a measurable cardinal, and at uncountable cofinalities the cardinals are downward absolute to  $K$  below  $0^\sharp$ . The results in this section answer most of the open questions raised in [Holy and Schlicht, 2018]. We also introduce the notion of *ideal-absolute* properties of forcings, being properties such that generic elementary embeddings can be characterised by ideals in the ground model. We show that several properties are ideal-absolute, which includes an improvement of an unpublished theorem of Foreman. This also results in another characterisation of completely ineffables.

---

## ACKNOWLEDGEMENTS

I want to thank my supervisor Philip Welch, both for offering valuable insights and guidance throughout this set theoretic journey, as well as for all the wonderful chats we have had over the years. Philip is the existence proof of it being possible for a professor to both be a brilliant academic as well as a wonderful human being.

I would also like to thank all my lovely postgraduate friends at the University of Bristol and abroad, who have made these past few years a great experience. Doing a PhD can be a lonely affair, so having such a network of like-minded friends to hang out with is invaluable.

A special thanks goes out to my friend Anne. Staying in touch with friends from abroad is tough, but with Anne it has been completely seamless. Living in a foreign culture without (initially) knowing anyone is daunting, and the amount of emotional support she has given me is priceless.

Lastly, I would like to thank Amy, who transformed the last phase of my PhD from being incredibly stressful, due to both the thesis as well as the worldwide COVID-19 pandemic, to being truly enjoyable.

---

## AUTHOR'S DECLARATION

I declare that the work in this dissertation was carried out in accordance with the requirements of the University's Regulations and Code of Practice for Research Degree Programmes and that it has not been submitted for any other academic award. Except where indicated by specific reference in the text, the work is the candidate's own work. Work done in collaboration with, or with the assistance of, others, is indicated as such. Any views expressed in the dissertation are those of the author.

# INTRODUCTION

Gödel proved his Incompleteness Theorems in [Gödel, 1931], one of which showed that to every consistent sufficiently strong<sup>1</sup> theory there would be statements which the system can neither prove nor disprove; we say that such a theory is *incomplete* and say that the statement in question is *independent* of the theory. Of notable importance is ZFC, the established foundational theory of Mathematics. Mathematicians at the time were generally disinterested in his result, as they considered the statement he constructed in his proof to be “unnatural” and therefore have no real consequence to mathematical practice.

Proceeding Gödel’s proof of the consistency of the *Continuum Hypothesis* in [Gödel, 1938], which was also the first problem that appeared on Hilbert’s famous list of 23 problems in Mathematics published in year 1900, Gödel proposed a program in [Gödel, 1947], the goal of which was to “decide interesting mathematical propositions independent of ZFC in well-justified extensions of ZFC.” His result had shown the “first half” for the Continuum Hypothesis, namely that ZFC cannot disprove it.

The second half of the proof that the Continuum Hypothesis is indeed independent of ZFC came about roughly two decades later, when Cohen used his newly developed notion of *forcing* in [Cohen, 1964] to prove the consistency of the *negation* of the Continuum Hypothesis, showing that there *are* natural statements which are independent of ZFC.

Today, many others have followed in Gödel’s footsteps and have made great efforts to analyse the nature of these natural independent statements. This organically led to the development of *large cardinal axioms*, being axioms that extend ZFC in terms of consistency strength and seem to be the *canonical* such axioms, in that all natural theories found “in the wild” have been shown to be equiconsistent with a known large cardinal axiom.

A notable phenomenon is that for “natural” theories  $T$  and  $U$ , if  $T$  has smaller consistency strength than  $U$  then the  $\Sigma^0_\omega$  consequences of  $T$  are also  $\Sigma^0_\omega$  consequences of  $U$  – so by climbing this large cardinal hierarchy we in fact uncover more truths about the natural numbers. The theory of the reals *also* attain this

---

<sup>1</sup>Being able to prove PA counts as “sufficiently strong”.

monotone behaviour as long as one has moved sufficiently far up the hierarchy, namely past the existence of infinitely many so-called *Woodin cardinals*. This phenomenon also occurs for the theory of certain sets of reals.

Now, it has been found that large cardinals having the strength of at least a measurable cardinal can be characterised in terms of *elementary embeddings*, enabling a uniform analysis of these cardinals. The large cardinals below the measurables have historically not had such uniform characterisations, but recently the notion of a *virtual large cardinal* was introduced in [Schindler, 2000a] and [Gitman and Schindler, 2018] that essentially *reflects* a lot of the behaviour of the larger large cardinals down to the lower realms. Here Cohen’s method of forcing is in full force, as the definition of a virtual version of a large cardinal characterised by elementary embeddings is essentially stating that we can *force* such an embedding to exist, rather than postulating their existence in the universe.

A motivation for studying these virtual large cardinals is that they allow us to utilise our current elementary embedding toolbox in more diverse contexts: we will see that all the virtual large cardinals are very weak in terms of consistency strength, which makes it possible to use methods from the theory of elementary embeddings to study weak theories of interest. Examples of these include the following:

**THEOREM 0.1** ([Schindler, 2000a] and [Schindler, 2004]). *The following are equiconsistent:*

- *There exists a virtually supercompact cardinal;*
- *The theory of  $L(\mathbb{R})$  cannot be changed by proper forcing;*
- *The theory of  $L(\mathbb{R})$  cannot be changed by semi-proper forcing.*

**THEOREM 0.2** ([Wilson, 2019a]). *The following are equiconsistent:*

- *There exists a virtually Vopěnka cardinal;*
- *$ZF + \ulcorner \Sigma_2^1 \urcorner$  is the class of all  $\omega_1$ -Suslin sets $\urcorner + \Theta = \aleph_2$ .*

**THEOREM 0.3** ([Schindler and Wilson, 2018]). *The following are equiconsistent:*

- *There exists a virtually Shelah cardinal;*
- *$ZF + \ulcorner \text{every universally Baire set of reals has the perfect set property} \urcorner$ .*

The study of the virtuals can also be used to analyse the opposite side of the large cardinal spectrum, namely the ones lying beyond the inconsistency border. The virtual versions of these are still consistency-wise very weak, allowing us to get

a glimpse into the nature of exotic large cardinals such as the *Reinhardt* and *Berkeley* cardinals, which are both inconsistent with ZFC (but it is currently unknown whether they are inconsistent with ZF).

This thesis is an extensive analysis of this virtual phenomenon. The thesis naturally splits into two parts, with the first part being an analysis of the virtuals in isolation and the second part being how these virtuals relate to commonly used set-theoretic objects. Chapter 2 covers the first part, and Chapters 3 and 4 the second.

In the first part we examine how the virtual large cardinals relate to each other, and highlights how they differ from their non-virtual counterparts. A crucial difference between the virtuals and the standard large cardinals is that we do not get a Kunen inconsistency for the virtuals. One consequence of this is that the property that  $j(\kappa) > \theta$  always holds when  $\kappa$  is a  $\theta$ -strong cardinal with  $j : V \rightarrow \mathcal{M}$  being the associated elementary embedding, does not always hold in the virtual world. This leads us to define *prestrong* cardinals as the cardinals not having this property, and in Theorem 2.10 we characterise the virtual  $\theta$ -prestrong cardinals into either virtually  $\theta$ -strong cardinals or virtually  $(\theta, \omega)$ -superstrong cardinals. One consequence of this is that virtually measurable cardinals are *equiconsistent* with virtually strong cardinals, without being equivalent. Another consequence is Corollary 2.53, that “virtualised Kunen inconsistencies”, being the existence of virtually rank-into-rank cardinals, happen exactly when we can separate the virtually prestrong cardinals from the virtually strong cardinals.

The virtual large cardinals also differ from the standard large cardinals by how they interact with structures closed under sequences. We first see this difference in Theorem 2.4, due to Ralf Schindler and Victoria Gitman, who showed that the virtually strong cardinals are equivalent to the virtually supercompact cardinals. This is expanded to virtually Woodin cardinals in Proposition 2.16, yielding a plethora of characterisations of these cardinals, as well as in Theorem 2.22, where we show that the Woodin cardinals and the Vopěnka cardinals are also equivalent in the virtual world. These two results are joint with Stamatis Dimopoulos and Victoria Gitman.

We next delve into a weak version of the Vopěnka principle, denoted WVP, which originates from category theory. Trevor Wilson has shown that WVP is equivalent to On being a Woodin cardinal, and we show that this equivalence *only* holds in the virtual world if we work with *pre-Woodin* cardinals, in analogy with the prestrongs mentioned above, as well as not explicitly requiring the target model to be well-founded. This result is joint with Victoria Gitman.

Since there are no Kunen inconsistencies in the virtual world, this allows us to study the virtual versions of the *Berkeley cardinals* in ZFC. We introduce these and show that in Theorem 2.43, the virtual Vopěnka principle implies that  $\text{On}$  is Mahlo *exactly* when there are no virtually Berkeley cardinals, improving on a result by Victoria Gitman and Joel Hamkins.

We furthermore show that the virtually Berkeley cardinals exist exactly when  $\text{On}$  is virtually pre-Woodin without being virtually Woodin, which parallels the result for the rank-into-rank cardinals mentioned above. This also hints at Berkeley cardinals being a natural large cardinal notion.

The virtual large cardinals all require the target model of the generic elementary embedding to be a subset of the ground model, and if we remove this condition then we get the *faint* large cardinals. We show in Corollary 2.52 that the virtuals and faints are consistently distinct notions. We provide further separations in Theorem 2.50, this theorem being joint with Victoria Gitman. However, in Theorem 2.46 we show that in  $L$ ,  $L[\mu]$  as well as in the core model  $K$  below a Woodin cardinal, the two notions are equivalent.

The first part ends with an analysis of indestructibility properties of the faints, which is joint with Philipp Schlicht. We work with a strengthening of the faintly supercompact cardinals in which the target model is closed under sequences in the generic extension and not just in the ground model. We show that these cardinals enjoy many indestructibility properties, including under  $<\kappa$ -directed closed forcings and  $\text{Add}(\omega, \kappa)$ . In an attempt to understand how strong these cardinals are, we show that no such cardinals can exist in neither  $L$  nor  $L[\mu]$ . Using the stationary tower we can show that a proper class of Woodin cardinals is an upper bound, but a recent unpublished result by Toshimichi Usuba shows that, surprisingly, virtually extendibles also provide an upper consistency bound for these cardinals.

The second part is split into two chapters. The first chapter explores filters and games and has been published in [Nielsen and Welch, 2019]. We perform a thorough analysis of certain Ramsey-like cardinals introduced in [Holy and Schlicht, 2018], defined using *filter games*, in which player I plays set-sized structures  $\mathcal{M}_\alpha$  and player II has to follow up with  $\mathcal{M}_\alpha$ -filters on the cardinal  $\kappa$  in question.

They focused on the case in which player I does not have a winning strategy, where they showed that this results in a large cardinal notion characterised by elementary embeddings between set-sized structures. Our main focus is when player II *does* have a winning strategy, and we answer almost all of the open questions in [Holy and Schlicht, 2018] regarding these.

When the games are of finite length we show in Theorems 3.21 and 3.23 that the resulting large cardinal notions form a strict hierarchy via the use of indescribability properties, and characterise in Theorem 3.30 the completely ineffable cardinals with these games.

As we move to infinite games this is when we reach the connection to the virtual large cardinals. Indeed, Theorem 3.31 shows that the faintly  $\theta$ -measurable cardinals can be characterised in terms of a slight weakening of the  $\omega$ -length version of these games. Theorem 3.33 shows that this weakened game is equivalent to the original game in  $L$ , and is related to the above-mentioned separation- and core model results. These two theorems are joint with Ralf Schindler.

Taking one more step, to games of length  $\omega + 1$ , our consistency strength suddenly dramatically increases to measurable cardinals, as shown in Theorem 3.47. For these countable length games we show that our resulting large cardinals can be characterised in terms of *indiscernible games* from [Sharpe and Welch, 2011]. We also include proofs due to Philip Welch and Ralf Schindler that the cardinals corresponding to the  $\omega_1$ -length games are measurable in  $K$  below  $0^\sharp$  and a Woodin cardinal, respectively.

The last case is when the games have length of uncountable cofinality, where we show that the resulting large cardinals are downward absolute to  $K$  below  $0^\sharp$ , the sharp of a strong cardinal. We also show how the cardinals relate to the *strongly*- and *super Ramsey*s introduced by Victoria Gitman.

The other chapter in this second part asks the question of when these cardinals characterised by generic elementary embeddings can equivalently be characterised by the existence of ideals in the ground model. To organise our results we define a poset property to be *ideal-absolute* if this holds for forcings having that property. We show in Theorem 4.7 that distributivity properties are ideal-absolute and Theorem 4.9 and the subsequent Corollary 4.12 show that  $(\kappa, \kappa)$ -distributive  $<\lambda$ -closure is also ideal-absolute, for  $\lambda \in [\omega_1, \kappa^+]$ . This main result is an improvement of the proof of an unpublished result due to Matthew Foreman, Theorem 4.8.

Building on these results, we give in Corollary 4.13 another characterisation of the completely ineffables, in terms of ideals, and in Theorem 4.15 and Corollary 4.16 we show that  $<\lambda$ -closure is also ideal-absolute. This ties in with the above-mentioned weakening of the games, also showing that these games characterise the  $<\lambda$ -closed faintly- and ideally measurables.

We end with a final chapter containing a range of open questions, continuing on from our results in this thesis.

## NOTATION

We will denote the class of ordinals by  $\text{On}$ . For  $X, Y$  sets we denote by  ${}^XY$  the set of all functions from  $X$  to  $Y$ . For an infinite cardinal  $\kappa$ , we let  $H_\kappa$  be the set of sets  $X$  such that the cardinality of the transitive closure of  $X$  is strictly less than  $\kappa$ .  $\text{ZF}^-$  will denote ZF with the Collection scheme but without the Power Set axiom, following the results of [Gitman et al., 2015]. We write GBC for Gödel-Bernays class theory with the Axiom of Choice, and GB for GBC without the Axiom of Choice. The symbol  $\perp$  will denote a contradiction and  $\mathcal{P}(X)$  denotes the power set of  $X$ . We will sometimes denote elementary embeddings  $\pi: (\mathcal{M}, \in) \rightarrow (\mathcal{N}, \in)$  by simply  $\pi: \mathcal{M} \rightarrow \mathcal{N}$ . Generally,  $\alpha, \beta, \gamma, \zeta$  will denote ordinals and  $\kappa, \lambda, \theta, \delta$  cardinals. We will always assume elementary embeddings to be non-trivial unless otherwise stated, meaning that the elementary embedding in question is not the identity. We will sometimes abuse notation and denote a generic extension  $V[g]$  by simply  $V^\mathbb{P}$ , where  $g \subseteq \mathbb{P}$  is  $V$ -generic.

# 1 | PRELIMINARIES

This chapter will give a rough overview of concepts that will be used in subsequent chapters. We start with briefly recalling properties regarding filters and elementary embeddings that we will be employing, as well as describing GBC Gödel-Bernays class theory. We then spend some time on large cardinal theory, as it plays a prominent role in understanding how the *virtual* large cardinals in Chapter 2 compares to the other large cardinals.

We will also routinely be working with the core model  $K$  throughout this thesis, so we include a section that will give a high-level overview of what  $K$  is and which key properties it has. The last section in these preliminaries will cover some results related to working with elementary embeddings in different forcing extensions, which tend to not be covered in standard textbooks. In the interest of brevity we will provide references rather than proofs of most of these results.

## 1.1 FILTERS AND ELEMENTARY EMBEDDINGS

When we are dealing with elementary embeddings between set-sized structures, we will usually be interested in structures of the following form:

**DEFINITION 1.1.** For a cardinal  $\kappa$ , a **weak  $\kappa$ -model** is a set  $\mathcal{M}$  of size  $\kappa$  satisfying that  $\kappa + 1 \subseteq \mathcal{M}$  and  $(\mathcal{M}, \in) \models \text{ZFC}^-$ . If furthermore  $\mathcal{M}^{<\kappa} \subseteq \mathcal{M}$ ,  $\mathcal{M}$  is a  **$\kappa$ -model**.<sup>1</sup> ◦

A proto-typical example of a weak  $\kappa$ -model is any  $\kappa$ -sized  $M \prec H_{\kappa^+}$ , as it is well-known that  $H_{\kappa^+}$  satisfies  $\text{ZFC}^-$ . We can get a  $\kappa$ -model from this by closing off  $M$  under  $<\kappa$ -sequences while maintaining being an elementary substructure of  $H_{\kappa^+}$ . Note that this only works if  $2^{<\kappa} = \kappa$  however, as otherwise the resulting structure would be too large.

---

<sup>1</sup>Note that our (weak)  $\kappa$ -models do not have to be transitive, in contrast to the models considered in [Gitman, 2011] and [Gitman and Welch, 2011]. Not requiring the models to be transitive was introduced in [Holy and Schlicht, 2018].

Embeddings between these weak  $\kappa$ -models can equivalently be phrased in terms of ultrafilters, or *measures*. Recall that  $\mu$  is an  $\mathcal{M}$ -measure if

$$(\mathcal{M}, \in, \mu) \models \ulcorner \mu \text{ is a } \kappa\text{-complete ultrafilter on } \kappa \urcorner.$$

Some common properties of such measures are the following:

**DEFINITION 1.2.** For a weak  $\kappa$ -model  $\mathcal{M}$ , an  $\mathcal{M}$ -measure  $\mu$  is...

- **weakly amenable** if  $x \cap \mu \in \mathcal{M}$  for every  $x \in \mathcal{M}$  with  $\text{Card}^{\mathcal{M}}(x) = \kappa$ ;
- **countably complete** if  $\bigcap \vec{X} \neq \emptyset$  for every  $\omega$ -sequence  $\vec{X} \in {}^\omega \mu$ . ◦

Weak amenability can equivalently be phrased in terms of a property concerning only the embedding.

**PROPOSITION 1.3** ([Kunen, 1969]). *Let  $\mathcal{M}$  be a weak  $\kappa$ -model,  $\mu$  an  $\mathcal{M}$ -measure and  $j : \mathcal{M} \rightarrow \mathcal{N}$  the ultrapower embedding. Then  $\mu$  is weakly amenable iff  $j$  is  $\kappa$ -powerset preserving, meaning that  $\mathcal{M} \cap \mathcal{P}(\kappa) = \mathcal{N} \cap \mathcal{P}(\kappa)$ .* ■

We will also be employing the following well-known result regarding set-sized embeddings:

**LEMMA 1.4** (Ancient Kunen Lemma). *Let  $\kappa$  be regular,  $\mathcal{M}, \mathcal{N}$  weak  $\kappa$ -models,  $\theta \in (\kappa, o(\mathcal{M}))$  a regular  $\mathcal{M}$ -cardinal, and  $\pi : \mathcal{M} \rightarrow \mathcal{N}$  an elementary embedding with  $\text{crit } \pi = \kappa$  and  $H_\theta^{\mathcal{M}} \subseteq \mathcal{N}$ . Then for every  $X \in H_\theta^{\mathcal{M}}$  with  $\text{card}^{\mathcal{M}}(X) = \kappa$  it holds that  $\pi \upharpoonright X \in \mathcal{N}$ .*

**PROOF.** Let  $f : \kappa \rightarrow X$ ,  $f \in \mathcal{M}$ , be a bijection and note that  $\pi(x) = \pi(f)(f^{-1}(x))$  for all  $x \in X$ , so it suffices that  $f, \pi(f) \in \mathcal{N}$ , which is true since  $f \in H_\theta^{\mathcal{M}} \subseteq \mathcal{N}$ . ■

## 1.2 GÖDEL-BERNAYS CLASS THEORY

As we will often find ourselves working with proper classes, we need to be able to work rigourously with these. We formalise this in second-order *Gödel-Bernays class theory*, GBC. In the following we will use the standard convention of using uppercase letters for classes and lowercase letters for sets.

**DEFINITION 1.5.** The axioms of **Gödel-Bernays set theory with Choice**, **GBC**, are as follows.

- (i) **ZFC**;
- (ii) (Class extensionality) Two classes are equal iff they have the same elements;
- (iii) (Class replacement) Every class-sized function restricted to a set is a set;
- (iv) (Class comprehension scheme) For classes  $Y_1, \dots, Y_m$  and every formula  $\varphi(v_1, \dots, v_n, V_1, \dots, V_m)$  that only quantifies over sets it holds that

$$\{(x_1, \dots, x_n) \mid \varphi[x_1, \dots, x_n, Y_1, \dots, Y_m]\}$$

is a class;

- (v) (Global choice) There is a class function  $G$  such that, for every non-empty set  $x$ ,  $G(x) \in x$ . ◦

**THEOREM 1.6** (Cohen-Kripke-Solovay; [Cohen, 1966]). *GBC is conservative over ZFC, meaning that if  $\sigma$  is a first-order sentence and  $GBC \vdash \sigma$  then  $ZFC \vdash \sigma$  as well. Intuitively speaking, GBC does not add new information about sets.* ■

### 1.3 LARGE CARDINALS

Since large cardinals came into existence in the beginning of the 20th century, a vast zoo of different types of such have appeared. The aim of this section is to act as a reference for the definitions of these as well as the relations between them.

Large cardinals are roughly split into two “sections”: the small ones and the large ones. This distinction is a bit blurry and varies from set theorist to set theorist, but here the distinction will be made at the point where *global elementary embeddings* enter the picture, which starts at the measurable cardinals.

We will start from the bottom and only cover the large cardinals that we will be dealing with in this thesis. See Figure 1.1 for an overview of these.

#### 1.3.1 Small large cardinals

The first large cardinal lies at the very bottom of the hierarchy: the inaccessibles.

**DEFINITION 1.7.** A cardinal  $\kappa$  is **regular** if  $\text{cof } \kappa = \kappa$ ; i.e. that there is no ordinal  $\gamma < \kappa$  with a cofinal function  $f: \gamma \rightarrow \kappa$ .  $\kappa$  is a **strong limit** if  $2^\lambda < \kappa$  for all

cardinals  $\lambda < \kappa$ . If  $\kappa$  is both regular and a strong limit then we say that it is (strongly) **inaccessible**. ◦

Every other large cardinal is either inaccessible or implies that there exists an inner model with an inaccessible cardinal. The following shows that inaccessible cardinals transcend ZFC:

**PROPOSITION 1.8** (Sierpiński-Tarski-Zermelo; [Kanamori, 2008] 1.2). *If  $\kappa$  is an inaccessible cardinal then  $(V_\kappa, \in) \models \text{ZFC}$ .* ■

Gödel's Second Incompleteness Theorem from [Gödel, 1931] then shows that ZFC can prove neither the existence of any inaccessible cardinals nor the mere consistency of inaccessible cardinals existing. This is the foundation of the large cardinal hierarchy. We say that a large cardinal is **stronger** than another large cardinal if the former proves the consistency of the latter, so that the same application of the Incompleteness Theorem shows that the weaker large cardinal theory can never prove the consistency of the stronger one.

Taking a tiny step further, we arrive at the (inaccessible)  $\Sigma_n$ -reflecting cardinals.

**DEFINITION 1.9.** For  $n < \omega$ , an inaccessible cardinal  $\kappa$  is  $\Sigma_n$ -**reflecting** if it holds that  $H_\kappa \prec_n V$ . ◦

Note that it is also common to not require inaccessibility of  $\Sigma_n$ -reflecting cardinals, in which case they are simply equiconsistent with ZFC by the Reflection Theorem. But as all our  $\Sigma_n$ -reflecting cardinals will be inaccessible in this thesis we include this in the definition.

**PROPOSITION 1.10** (Folklore). *For  $n \geq 2$ , every  $\Sigma_n$ -reflecting cardinal is a limit of inaccessible cardinals.*

**PROOF.** Let  $\kappa$  be  $\Sigma_n$ -reflecting. Note that the definitions of both regularity and strong limit are  $\Pi_1$ -formulae, making inaccessibility  $\Pi_1$  as well. But now we get that, for every  $\xi < \kappa$ ,  $V \models \exists \lambda > \xi: \ulcorner \lambda \text{ is inaccessible} \urcorner$ . This statement is a

$\Sigma_2$ -sentence, so since we in particular have that  $H_\kappa \prec_2 V$  it holds that

$$H_\kappa \models \exists \lambda > \xi: \ulcorner \lambda \text{ is inaccessible} \urcorner.$$

We can therefore define a sequence of inaccessible cardinals  $\langle \lambda_\alpha \mid \alpha < \kappa \rangle$  with  $\lambda_0$  being the least inaccessible below  $\kappa$ ,  $\lambda_{\alpha+1}$  being the least inaccessible cardinal in  $(\lambda_\alpha, \kappa)$ , and  $\lambda_\gamma$  being the least inaccessible cardinal in  $[\sup_{\alpha < \gamma} \lambda_\alpha, \kappa)$  for  $\gamma < \kappa$  a limit ordinal. These exist by regularity of  $\kappa$  and since a cardinal  $\lambda < \kappa$  is inaccessible iff  $H_\lambda \models \ulcorner \lambda \text{ is inaccessible} \urcorner$  by  $\Sigma_1$ -reflection. ■

Next, we move a handful of steps up the large hierarchy ladder and introduce the *weakly compact cardinals*. These have a multitude of different equivalent definitions which we will not cover here, but instead define them in terms of a combinatorial colouring relation. We need a definition.

**DEFINITION 1.11.** For any function  $f: A \rightarrow B$ , a subset  $H \subseteq A$  is **homogeneous for  $f$**  if  $f \upharpoonright H$  is a constant function. ◻

We may think of  $f$  in the above Definition 1.11 as being a *colouring function* that colours elements of  $A$  in colours taken from  $B$ . For  $H \subseteq A$  to be homogeneous would then mean that everything in  $H$  has the same colour.

**DEFINITION 1.12.** An uncountable cardinal  $\kappa$  is **weakly compact** if to every function  $f: [\kappa]^2 \rightarrow \{0, 1\}$  there is a  $H \subseteq [\kappa]^2$  of size  $\kappa$  which is homogeneous for  $f$ . ◻

Again, thinking in terms of colourings,  $\kappa$  is weakly compact if whenever we colour pairs of ordinals below  $\kappa$  in two colours, then we can find a large (i.e. of size  $\kappa$ ) set of such pairs all of the same colour.

The following result then shows that the weakly compact cardinals are indeed stronger than the inaccessibles:

**THEOREM 1.13** (Erdős-Tarski; [Jech, 2006] 9.9). *Every weakly compact cardinal is a limit of inaccessible cardinals.* ■

Moving a tiny step further, we introduce two strengthenings of the weakly compacts: the *ineffables* and the *completely ineffables*.

**DEFINITION 1.14.** An uncountable cardinal  $\kappa$  is **ineffable** if there to any function  $f: [\kappa]^2 \rightarrow 2$  exists a *stationary*  $H \subseteq [\kappa]^2$  which is homogeneous for  $f$ .  $\circ$

Ineffable cardinals are weakly compact by definition, and the following theorem from [Friedman, 2001] shows that they are strictly stronger:

**THEOREM 1.15** (Friedman). *Ineffable cardinals are weakly compact limits of weakly compacts.*  $\blacksquare$

A way of improving ineffability is to “close under homogeneity”, in the sense that if  $H$  is homogeneous for  $f: [\kappa]^2 \rightarrow 2$  and  $g: [H]^2 \rightarrow 2$  is any function, then there is a subset of  $H$  which is homogeneous for  $g$ . To formalise this notion we use the concept of a *stationary class*.

**DEFINITION 1.16.** For  $X$  any set, a set  $\mathcal{R} \subseteq \mathcal{P}(X)$  is a **stationary class** if

- $\mathcal{R} \neq \emptyset$ ;
- Every  $A \in \mathcal{R}$  is a stationary subset of  $X$ ;
- If  $A \in \mathcal{R}$  and  $B \supseteq A$  then  $B \in \mathcal{R}$ .  $\circ$

**DEFINITION 1.17.** An uncountable cardinal  $\kappa$  is **completely ineffable** if there is a stationary class  $\mathcal{R} \subseteq \mathcal{P}(\kappa)$  such that for every  $A \in \mathcal{R}$  and  $f: [A]^2 \rightarrow 2$  there exists a  $H \in \mathcal{R}$  which is homogeneous for  $f$ .  $\circ$

As suspected, these completely ineffable cardinals are indeed strictly stronger than the ineffables, as the following theorem shows:

**THEOREM 1.18** ([Abramson et al., 1977]). *Completely ineffable cardinals are ineffable limits of ineffable cardinals.*  $\blacksquare$

The next kind of large cardinal involves elementary embeddings. To motivate the definition we note the following characterisation of the weakly compact cardinals:

**THEOREM 1.19** ([Hauser, 1991]). *An uncountable cardinal  $\kappa$  is weakly compact if and only if for every  $A \subseteq \kappa$  there exist weak  $\kappa$ -models  $\mathcal{M}, \mathcal{N}$  with  $A \in \mathcal{M}$  and an elementary embedding  $\pi: \mathcal{M} \rightarrow \mathcal{N}$  with  $\text{crit } \pi = \kappa$ .* ■

We would arrive at a natural strengthening of this characterisation if we require more agreement between  $\mathcal{M}$  and  $\mathcal{N}$ , leading to the following definition:

**DEFINITION 1.20** ([Gitman, 2011]). An uncountable cardinal  $\kappa$  is **1-iterable** if to every subset  $A \subseteq \kappa$  there exists a weak  $\kappa$ -model  $\mathcal{M}$  such that  $A \in \mathcal{M}$  and there exists a weakly amenable  $\mathcal{M}$ -measure  $\mu$  on  $\kappa$  such that  $\text{Ult}(\mathcal{M}, \mu)$  is wellfounded. ○

In the same paper, Gitman shows that these large cardinals are indeed consistency-wise stronger than the completely ineffables.

**THEOREM 1.21** ([Gitman, 2011]). *Every 1-iterable cardinal is a limit of completely ineffable cardinals.* ■

Lastly, the *Ramsey cardinals* are natural strengthenings of the weakly compacts.

**DEFINITION 1.22.** An uncountable cardinal  $\kappa$  is **Ramsey** if there to every function  $f: [\kappa]^{<\omega} \rightarrow \{0, 1\}$  exists a subset  $H \subseteq [\kappa]^{<\omega}$  such that, for every  $n < \omega$ ,  $H \cap [\kappa]^n$  is homogeneous for  $f \restriction [\kappa]^n$ . ○

See Figure 1.1 for an overview of all the large cardinals covered in this section.

### 1.3.2 Large large cardinals

Moving on to the higher reaches of the large cardinals, these are more uniformly defined and all involve elementary embeddings. Our first type of large large cardinal is the measurable cardinal, being the first cardinal witnessing an elementary embedding from the entire universe. We formalise this in GBC, defined in Section 1.2.

**DEFINITION 1.23** (GBC). An uncountable cardinal  $\kappa$  is **measurable** if there exists a transitive class  $\mathcal{M}$  and an elementary embedding  $j: (V, \in) \rightarrow (\mathcal{M}, \in)$  with critical point  $\kappa$ . ○

The measurable cardinals were the first cardinals shown to “transcend” Gödel’s constructible universe  $L$ .<sup>2</sup> This was proven by Dana Scott and has now become known as Scott’s Theorem.<sup>3</sup>

**THEOREM 1.24** (Scott’s Theorem; [Kanamori, 2008] 5.5).  *$L$ , Gödel’s constructible universe, has no measurable cardinals.* ■

Given this result, it is not surprising that the measurables then exceed the strength of the previous large cardinals.

**PROPOSITION 1.25.** *Measurable cardinals are completely ineffable limits of completely ineffable cardinals.*

**PROOF.** (Sketch) If  $j: V \rightarrow \mathcal{M}$  is a non-trivial elementary embedding then the **derived ultrafilter**  $\mu \subseteq \mathcal{P}(\kappa)$  on  $\kappa := \text{crit } j$  is defined as  $X \in \mu$  iff  $\kappa \in j(X)$ . Section 5 in [Kanamori, 2008] shows that it is indeed an ultrafilter and that its ultrapower  $\text{Ult}(V, \mu)$  is wellfounded. A reflection argument then shows that we can simply take  $\mathcal{R} := \mu$ . ■

Moving even further, we strengthen the definition of measurable cardinals to arrive at the *strong cardinals*.

**DEFINITION 1.26** (GBC). An uncountable cardinal  $\kappa$  is **strong** if there to every cardinal  $\theta > \kappa$  exists a transitive class  $\mathcal{M}_\theta$  satisfying that  $H_\theta \subseteq \mathcal{M}_\theta$ , and an elementary  $j_\theta: (V, \in) \rightarrow (\mathcal{M}_\theta, \in)$  with critical point  $\kappa$ . We say that  $\kappa$  is  **$\theta$ -strong** if the property holds for a specific  $\theta$ . ○

**PROPOSITION 1.27** (Gaifman, [Kanamori, 2008] 26.6). *Strong cardinals are measurable limits of measurable cardinals.* ■

One property of the strong cardinals that we will get back to in the next subsection and which will be important in Chapter 2 is the following:

<sup>2</sup>For more information about  $L$ , see e.g. [Schindler, 2014]

<sup>3</sup>The measurables are not the weakest large cardinals with this property, however. For instance, the Ramsey cardinals enjoy this property too, but none of the other large cardinals described in the previous subsection enjoys this property.

**PROPOSITION 1.28** ([Kanamori, 2008] 26.7). *If  $j: V \rightarrow \mathcal{M}_\theta$  witnesses that  $\kappa := \text{crit } j$  is a  $\theta$ -strong cardinal then  $j(\kappa) > \theta$ .* ■

We can strengthen the strongs even more by requiring *sequence closure* rather than only containing an initial segment of the universe.

**DEFINITION 1.29** (GBC). An uncountable cardinal  $\kappa$  is **supercompact** if there to every cardinal  $\theta > \kappa$  exists a transitive class  $\mathcal{M}_\theta$  satisfying that  $^{<\theta} \mathcal{M}_\theta \subseteq \mathcal{M}_\theta$ , and an elementary  $j_\theta: (V, \in) \rightarrow (\mathcal{M}_\theta, \in)$  with critical point  $\kappa$ . ◻

To get an intuition of why the sequence closure is a lot more powerful, note that bits of the elementary embedding itself are now elements of  $\mathcal{M}_\theta$ , so that  $\mathcal{M}_\theta$  can now start reasoning about large cardinals and,  $j_\theta$  being elementary, these facts will then be carried back into the universe. Here is an example of such an argument.

**PROPOSITION 1.30.** *If  $\kappa$  is supercompact then*

$$V_\kappa \models \ulcorner \text{There exists a proper class of strong cardinals} \urcorner. \quad (1)$$

**PROOF.** (Sketch) By noting that the restrictions of the supercompact embedding is an element of the target model by supercompactness,  $\kappa$  is strong up to  $j(\kappa)$  in the target model, so that a reflection argument shows (1). ■

[Magidor, 1971] introduced the following equivalent definition of supercompactness<sup>4</sup>:

**DEFINITION 1.31.** A cardinal  $\kappa$  is supercompact iff for every regular  $\theta > \kappa$  there is a  $\bar{\theta} < \kappa$  and an elementary embedding  $\pi: H_{\bar{\theta}} \rightarrow H_\theta$  with  $\pi(\text{crit } \pi) = \kappa$ . ◻

Another way of strengthening the strong cardinals is by restricting the behaviour of what the elementary embedding can do on certain sets.

**DEFINITION 1.32.** Let  $A$  be any (potentially proper) class. An uncountable cardinal  $\kappa$  is  **$A$ -strong** if there to every cardinal  $\theta > \kappa$  exists a transitive class  $\mathcal{M}_\theta$  satisfying

---

<sup>4</sup>See Theorem 22.10 in [Kanamori, 2008] for a proof.

that  $H_\theta \subseteq \mathcal{M}_\theta$ , and an elementary  $j_\theta: (V, \in) \rightarrow (\mathcal{M}_\theta, \in)$  with critical point  $\kappa$ , such that  $A \cap H_\theta = j(A) \cap H_\theta$ .<sup>5</sup>  $\circ$

These  $A$ -strong cardinals are not used much in practice, but the following *Woodin cardinals* are immensely useful and can be seen as a “local” version of a proper class of  $A$ -strongs for every class  $A$ :

**DEFINITION 1.33.** An uncountable cardinal  $\delta$  is a **Woodin cardinal** if there to every subset  $A \subseteq H_\delta$  exists a cardinal  $\kappa < \delta$  such that  $(H_\delta, \in, A) \models \ulcorner \kappa \text{ is } A\text{-strong} \urcorner$ .  $\circ$

Woodin cardinals can equivalently be defined in terms of functions instead of the  $A$ -strong cardinals.

**THEOREM 1.34** (Woodin; [Kanamori, 2008] 26.14). *The following are equivalent for an uncountable cardinal  $\kappa$ :*

- (i)  $\kappa$  is a Woodin cardinal;
- (ii) For any  $f: \kappa \rightarrow \kappa$  there exists  $\alpha < \kappa$  such that  $f[\alpha] \subseteq \alpha$ , a transitive  $\mathcal{M}$  with  $V_{j(f)(\alpha)} \subseteq \mathcal{M}$  and an elementary embedding  $j: (V, \in) \rightarrow (\mathcal{M}, \in)$  with  $\text{crit } j = \kappa$ .

Our last large cardinal in this section is ostensibly completely different from the others. It originates from category theory, and according to [Pudlak, 2013] was originally proposed by Petr Vopěnka as a “bogus large cardinal property” which he believed was inconsistent with ZFC, but a proof of this never appeared.

**DEFINITION 1.35** (GBC). **Vopěnka’s Principle (VP)** postulates that to any first-order language  $\mathcal{L}$  and proper class  $\mathcal{C}$  of  $\mathcal{L}$ -structures, there exist distinct  $\mathcal{M}, \mathcal{N} \in \mathcal{C}$  and an elementary embedding  $j: \mathcal{M} \rightarrow \mathcal{N}$ .  $\circ$

**DEFINITION 1.36.** An uncountable cardinal  $\delta$  is **Vopěnka** if  $(V_\delta, \in; V_{\delta+1}) \models \text{VP}$ .  $\circ$

Perlmutter showed that the Woodin- and Vopěnka cardinals are closely connected, with Woodin cardinals relating to Vopěnka cardinals in the same way that strong cardinals relate to supercompacts.

---

<sup>5</sup>When  $A$  is a proper class then  $j(A)$  is short for the proper class  $\bigcup_{\theta \in \text{On}} j(A \cap H_\theta)$ .

**THEOREM 1.37** ([Perlmutter, 2015]). *Vopěnka cardinals are equivalent to cardinals  $\delta$  that are “Woodin for supercompactness”, meaning that to any subset  $A \subseteq H_\delta$  there is a cardinal  $\kappa < \delta$  with  $(H_\delta, \in, A) \models \ulcorner \kappa \text{ is } A\text{-supercompact} \urcorner$ .*<sup>6</sup> ■

See Figure 1.1 for an overview of all the large cardinals covered in this section.

### 1.3.3 Inconsistent large cardinals

In these highest reaches of the large cardinal hierarchy we encounter large cardinals whose existence are inconsistent with ZFC. The reason why these are still interesting to us is because none of them have yet been proven inconsistent with ZF. The first such cardinal is the following:

**DEFINITION 1.38** (GBC). An uncountable cardinal  $\kappa$  is a **Reinhardt cardinal** if there exists an elementary embedding  $j: (V, \in) \rightarrow (V, \in)$  with  $\text{crit } j = \kappa$ . ◻

This was shown to be inconsistent in [Kunen, 1971].

**THEOREM 1.39** (Kunen inconsistency; GBC; [Kanamori, 2008] 23.12). *There is no non-trivial elementary  $j: (V_{\lambda+2}, \in) \rightarrow (V_{\lambda+2}, \in)$  for any uncountable cardinal  $\lambda$ . In particular, there is no Reinhardt cardinal.*

The proof of Proposition 1.28, which stated that  $j(\kappa) > \theta$  always holds for strong cardinals  $\kappa$ , relies heavily on the Kunen inconsistency. When we are going to deal with the *virtual* large cardinals in Chapter 2 we do not have such a Kunen inconsistency and we will show that in that case the property  $j(\kappa) > \theta$  is a highly non-trivial assumption.

There is also the following strengthening of the Reinhardts, in analogy with the strong cardinals:

**DEFINITION 1.40.** An uncountable cardinal  $\kappa$  is **super Reinhardt** if for all ordinals  $\lambda$  there exists an elementary embedding  $j: (V, \in) \rightarrow (V, \in)$  with  $\text{crit } j = \kappa$  and  $j(\kappa) > \lambda$ . ◻

---

<sup>6</sup>Here  $\kappa$  is, in analogy with Definition 1.32, *A-supercompact* if there to every cardinal  $\theta > \kappa$  exists a transitive class  $\mathcal{M}_\theta$ , closed under  $<\theta$ -sequences, and an elementary  $j_\theta: (V, \in) \rightarrow (\mathcal{M}_\theta, \in)$  with critical point  $\kappa$ , such that  $A \cap H_\theta = j(A) \cap H_\theta$ .

We can improve this even further by defining a notion corresponding to Woodin cardinals. If we define  $\kappa$  to be ***A*-super Reinhardt** for a class  $A$  to be a super Reinhardt cardinal with  $\bigcup_{\alpha \in \text{On}} j(A \cap V_\alpha) = A$ , in analogy with the  $A$ -strong cardinals, then we define the *totally Reinhardts* as follows.

**DEFINITION 1.41.** An inaccessible cardinal  $\kappa$  is **totally Reinhardt** if for each  $A \subseteq V_\kappa$  it holds that

$$(V_\kappa, \in; V_{\kappa+1}) \models \ulcorner \text{There exists an } A\text{-super Reinhardt cardinal} \urcorner. \quad \circ$$

The last large cardinals that we will introduce are the Berkeley cardinals. These were introduced by Woodin at University of California, Berkeley around 1992. Similar to the Vopěnka cardinals, these were introduced as a large cardinal candidate that would “clearly” be inconsistent with ZF, but such a result has not yet been found. They imply the Kunen inconsistency and are therefore at least inconsistent with ZFC, but that is as far as it currently goes.

We start with a preliminary definition.

**DEFINITION 1.42 (GB).** An uncountable cardinal  $\delta$  is a **proto-Berkeley cardinal** if to every transitive set  $\mathcal{M}$  such that  $\delta \subseteq \mathcal{M}$  there exists an elementary embedding  $j: (\mathcal{M}, \in) \rightarrow (\mathcal{M}, \in)$  with  $\text{crit } j < \delta$ . ◦

To see that these indeed imply the Kunen inconsistency, note that we in particular get an elementary embedding  $\pi: V_{\gamma+2} \rightarrow V_{\gamma+2}$ , which is inconsistent by Corollary 23.14 in [Kanamori, 2008].

Note that if  $\kappa$  is a proto-Berkeley cardinal then every  $\lambda > \kappa$  is also proto-Berkeley, which makes it quite an uninteresting notion. But we can isolate the interesting cases, leading to the definition of a Berkeley cardinal.

**THEOREM 1.43** ([Cutolo, 2017] 2.1.14). *If  $\delta_0$  is the least proto-Berkeley cardinal then we can choose the critical point of the embedding to be arbitrarily large below  $\delta_0$ .*

■

As this property is clearly not preserved upwards, this makes for a good candidate for the large cardinal notion.

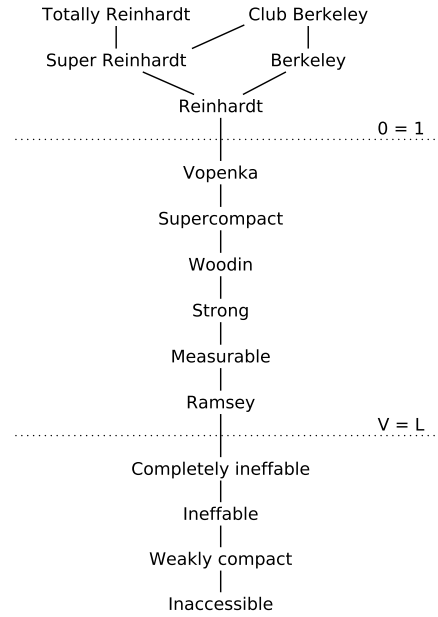

Figure 1.1: A subset of the large cardinal hierarchy, with lines indicating relative consistency implications.

**DEFINITION 1.44 (GB).** A proto-Berkeley cardinal  $\delta$  is **Berkeley** if we can choose the critical point of the embedding to be arbitrarily large below  $\delta$ . If we furthermore can choose the critical point as an element of any club  $C \subseteq \delta$  then we say that  $\delta$  is **club Berkeley**. ◦

In [Cutolo, 2017], the author furthermore mention that, among the above-mentioned cardinals, the non-trivial relative consistency implications currently known are the following:

**THEOREM 1.45** ([Cutolo, 2017] 2.2.1). *Berkeley cardinals are consistency-wise strictly stronger than Reinhardt cardinals.* ■

**THEOREM 1.46** ([Cutolo, 2017] 2.2.2). *Club Berkeley cardinals are consistency-wise strictly stronger than super Reinhardt cardinals.* ■

See Figure 1.1 for an overview of all the large cardinals covered in this section.

## 1.4 CORE MODEL THEORY

As we will be utilising the core model at various points throughout this thesis, we give here an idea of what we mean by the *core model*. A convenient feature of core model theory is that most of the technical details regarding the construction is not needed for applications; it suffices to know only its abstract properties. That being said, we *will* provide a glimpse of the construction at the end of this section. To see the full construction we refer the interested reader to [Nielsen, 2016], [Zeman, 2001] and [Jensen and Steel, 2013].

### 1.4.1 The core model $K$

The **core model**<sup>7</sup>  $K$  of a universe is roughly speaking the subuniverse that strikes a balance between retaining the complexity of the universe while being as simple as possible. The problem is then making all of this precise. Some aspects of the definition is agreed upon by most researchers:

- (i) We choose to define the *complexity* of a universe by its large cardinal structure. This is based on the empirical fact that large cardinals seem to capture the strength of every “naturally defined” hypothesis, and gives us a convenient yard stick. For instance, a universe containing a measurable cardinal is more complex than  $L$ , as Scott’s Theorem 1.24 shows that  $L$  cannot contain any measurable cardinals (or any large cardinals stronger than measurables);
- (ii) We further postulate that  $L$  is the simplest universe there is, and the simplicity of a universe should therefore be measured in terms of how much it resembles  $L$ . We will be more precise about what it means to “resemble  $L$ ” below, but with this intuitive notion it should at least be clear that, say,  $L$  is simpler than  $L[\mu]$ .

Even though (i) captures what we mean by complexity, it leaves much to be desired. For instance, as the structure of the large cardinal hierarchy can only be verified empirically, we might end up in an unfortunate situation where we simply do not know whether a given universe is more complex than another one<sup>8</sup>. The famous example of this is the current situation with the superstrong and strongly compact

---

<sup>7</sup> $K$  is short for *Kern*, meaning *core* in German.

<sup>8</sup>It might also be the case that the large cardinal hierarchy is not linear at all.

cardinals, that we simply do not know which one is stronger<sup>9</sup>. Thus, given a universe whose strength corresponds to that of a strongly compact and another one at the level of superstrongs, we would not be able to say which one is more complex.

To remedy this situation, we choose instead to define the complexity of a universe in terms of an intermediate property. A universe satisfying this property should then entail that it inherits the large cardinal structure of its surrounding universe. All the intermediate properties currently being used are all instances of a general phenomenon called *covering*. The intuitive idea is that every set in the universe can be “approximated” by a set in the subuniverse, and arose from a seminal theorem of Jensen, see [Schindler, 2014, 11.56], stating that  $0^\sharp$  exists if and only if *strong covering* fails for  $L$ , defined as follows.

**DEFINITION 1.47** (Jensen). We say that **strong covering** holds for universes  $\mathcal{U} \subseteq \mathcal{V}$  if to every  $\alpha < o(\mathcal{V})$  and  $X \in \mathcal{P}^\mathcal{V}(\alpha)$  with  $\text{Card}^\mathcal{V}(X) \geq \aleph_1^\mathcal{V}$  there exists  $A \in \mathcal{U}$  such that  $X \subseteq A$  and  $\text{Card}^\mathcal{V}(X) = \text{Card}^\mathcal{V}(A)$ .  $\circ$

We can then interpret Jensen’s result as saying that, if the complexity of the surrounding universe  $\mathcal{V}$  is below the strength of  $0^\sharp$  then  $L$  is a good candidate for  $K$ . In a complex universe we would therefore be looking for the core model among subuniverses more complex than  $L$ , and it turns out that also requiring strong covering to hold in such models is too much to ask; the current definition of covering has thus been weakened to the following:

**DEFINITION 1.48.** We say that **(weak) covering** holds for universes  $\mathcal{U} \subseteq \mathcal{V}$  if  $\text{cof}^\mathcal{V}(\alpha^{+\mathcal{U}}) = \text{Card}^\mathcal{V}(\alpha^{+\mathcal{U}})$  holds for any ordinal  $\alpha$  with  $\alpha^{+\mathcal{U}} \geq \aleph_2^\mathcal{V}$ .  $\circ$

This statement might seem very distant from the strong version, but one can think of weak covering as saying that  $\mathcal{U}$  “knows” the true cofinality of its successor cardinals  $\kappa \geq \aleph_2^\mathcal{V}$  within the error margin  $\varepsilon := \kappa^{+\mathcal{U}} - \text{Card}^\mathcal{V}(\kappa^{+\mathcal{U}})$ . More concretely, we could equivalently define weak covering as  $\mathcal{U}$  containing all cofinal maps  $f: \gamma \rightarrow \kappa$  in  $\mathcal{V}$  for every  $\gamma \in \text{Card}^\mathcal{V}(\kappa)$ , making it closer in spirit to the strong covering property.

---

<sup>9</sup>Although the general consensus is that the strongly compact cardinals should be equiconsistent with the supercompacts, making them stronger than the superstrongs.

Figure 1.2: Weak covering property

When it comes to (ii) we have to define what we mean by “resembling  $L$ ”. Ultimately this boils down to the current working definition of a *mouse* and is still a work in progress. If our universe is no more complex than the strength of a Woodin cardinal however, then we know what the correct definition of a mouse is, and hence also what “resembling  $L$ ” would mean in this context. The definition of mice along with the assumption of covering then turns out to imply that the core model will indeed inherit the large cardinal strength of the universe<sup>10</sup>.

To construct the core model one could then take a bottom-up approach, starting with  $L$  and then carefully include the complexity of the universe while remaining similar to  $L$ <sup>11</sup>. Alternatively, a top-down approach would be to define a structure which has *all* the complexity of the universe, and then showing that this structure indeed exhibits these  $L$ -like properties<sup>12</sup>.

<sup>10</sup>To show this one first uses covering to show that  $K$  is *universal*, i.e. that it wins every coiteration. With universality at hand, a comparison argument with any  $L[\vec{E}]$ -model containing a large cardinal will then show that  $K$  will have an inner model with the large cardinal in question.

<sup>11</sup>This strategy has a long history and current leading figures following it are Steel and Sargsyan.

<sup>12</sup>Woodin is pursuing this path.

### 1.4.2 Constructing $K$

The standard construction of  $K$  takes the bottom-up approach. The first step towards this is the construction of  $K^c$ ,<sup>13</sup> which we build by recursion on the ordinals. We start with  $K_0^c := \emptyset$  and at every successor ordinal  $\alpha$  we do one of two things:

- (i) If there exists a “nice” extender indexed at  $\alpha$  then we put it onto the extender sequence of  $\mathfrak{C}(K_\alpha^c)$ , where  $\mathfrak{C}(X)$  is the transitive collapse of a certain hull of  $X$ ,<sup>14</sup>
- (ii) Otherwise we let  $K_\alpha^c := \mathcal{J}(\mathfrak{C}(K_{\alpha-1}^c))$ , with  $\mathcal{J}(x) := \text{rud}(\text{trcl}(x \cup \{x\}))$  being the usual operator we use to build  $L$  with Jensen’s hierarchy.

In other words, we are essentially building  $L$  with extenders attached onto it in a canonical fashion. Taking cores at every step will ensure that the initial segments will be *sound*, which ultimately is what guarantees iterability of  $K^c$ . The fact that we put on all the relevant extenders from  $V$  is what will ensure the covering property of the model. It turns out that  $K^c$  is not exactly what we want however, as it relies *too much* on the surrounding universe, in contrast with  $L$  whose construction procedure builds the exact same model in every universe. To attain this *canonicity* we are again taking certain “thick” hulls of  $K^c$  (again, think of it as removing the noise). The resulting construction *almost* gives us what we want and is dubbed *pseudo-K*. The problem with this is that the technicalities of the construction uses certain properties of a fixed cardinal  $\Omega$ , so to build the true core model we “glue” these pseudo-K’s together.

The takeaway here is that whenever we are working with an initial segment of  $K$  then that segment will be built using the recursive steps (i) and (ii) above, carefully including extenders from  $V$ . For more details, see [Jensen and Steel, 2013] or [Nielsen, 2016].

### 1.4.3 Properties of $K$

In terms of applications of core model theory, the properties of  $K$  are usually what matters. We touched on the weak covering property above, but for completeness we state most of the properties usually employed when working with  $K$ .

<sup>13</sup>The “c” stands for *certified*, as the extenders we put on the sequence was historically called *certified extenders*.

<sup>14</sup>Think of  $\mathfrak{C}(X)$  as “removing the noise of  $X$ ”.

In [Jensen and Steel, 2013] they isolate a set of properties of  $K$  which leads them to *define*  $K$  as the structure satisfying the conjunction of these properties. These are as follows.<sup>15</sup>

- (i)  $K$  is a transitive proper class premouse satisfying ZFC;
- (ii)  $K$  is  $\Sigma_2$ -definable;
- (iii)  $K$  has a  $\Sigma_2$ -definable iteration strategy  $\Sigma$ ;
- (iv)  $K$  is **generically absolute**, meaning that  $K^V = K^{V[g]}$  and  $\Sigma^{V[g]} \upharpoonright V = \Sigma^V$  for any  $V$ -generic filter  $g \subseteq \mathbb{P}$  for a set-sized forcing notion  $\mathbb{P}$ ;
- (v)  $K$  is **inductively defined**, meaning that  $K \restriction \omega_1^V$  is  $\Sigma_1$ -definable over  $J_{\omega_1}(\mathbb{R})$ ;
- (vi)  $K$  satisfies **weak covering** as in Definition 1.48.

On top of these properties, we will also employ the following property, which is proven in Lemmata 7.3.7–7.3.9 and 8.3.4 in [Zeman, 2001]:

**THEOREM 1.49** (Zeman). *Assume  $0^\sharp$  does not exist. If  $\mu$  is a countably complete weakly amenable  $K$ -measure then  $\mu \in K$ .* ■

#### 1.4.4 Coiterations of mice

One of the crucial lemmata in the theory of mice, of which  $K$  is a special case, is the comparison lemma. Intuitively, it says that any two mice  $\mathcal{M}, \mathcal{N}$  can be *compared*, in the sense that we can transform  $\mathcal{M}$  and  $\mathcal{N}$  into new mice  $\hat{\mathcal{M}}$  and  $\hat{\mathcal{N}}$ , respectively, such that either  $\hat{\mathcal{M}}$  is an initial segment of  $\hat{\mathcal{N}}$  or vice versa. Such a transformation is called a **coiteration**, which can be thought of as being successive applications of measures in the mice, forming iterative ultrapowers. For more details regarding mice and coiterations, see [Steel, 2010] or [Nielsen, 2016].

**LEMMA 1.50** (Comparison lemma). *Let  $\theta$  be an uncountable regular cardinal or  $\theta = \text{On}$ . Let  $\mathcal{M}$  and  $\mathcal{N}$  be sound mice of size  $\leq \theta$ . Then there are iterations  $\mathcal{T}$  and  $\mathcal{U}$  of  $\mathcal{M}$  and  $\mathcal{N}$  having last models  $\hat{\mathcal{M}}$  and  $\hat{\mathcal{N}}$ , respectively, such that either*

- (i)  $\hat{\mathcal{M}} \trianglelefteq \hat{\mathcal{N}}$  and there is an elementary embedding  $\pi: \mathcal{M} \rightarrow \hat{\mathcal{M}}$ ; or
- (ii)  $\hat{\mathcal{N}} \trianglelefteq \hat{\mathcal{M}}$  and there is an elementary embedding  $\pi: \mathcal{N} \rightarrow \hat{\mathcal{N}}$ . ■

<sup>15</sup>See [Steel, 2010] for definitions of premice, iteration trees and iteration strategies.

## 1.5 FORCING LEMMATA

In this section we will cover a few results that we will need when working with elementary embeddings in different forcing extensions. These are the *lifting criterion*, which characterises when we can lift an elementary embedding to a forcing extension, *countable embedding absoluteness*, which allows us to “transfer” elementary embeddings from one forcing extension to another, and lastly a result that gives a sufficient condition for preserving sequence closure when moving to generic extensions.

### 1.5.1 Lifting criterion

When we are working with an elementary embedding  $\pi: \mathcal{M} \rightarrow \mathcal{N}$  between sets in the universe, we would sometimes like to lift such an embedding to a generic extension, meaning that given a forcing notion  $\mathbb{P} \in \mathcal{M}$  and an  $\mathcal{M}$ -generic  $g \subseteq \mathbb{P}$ , we are interested in when we can lift  $\pi$  to an embedding

$$\pi^+: \mathcal{M}[g] \rightarrow \mathcal{N}[h],$$

where  $h \subseteq \pi(\mathbb{P})$  is  $\mathcal{N}$ -generic. The **lifting criterion** shows exactly when this is possible.

**PROPOSITION 1.51** (The Lifting Criterion; [Cummings, 2010] 9.1). *Let  $\pi: \mathcal{M} \rightarrow \mathcal{N}$  be an elementary embedding between weak  $\kappa$ -models. Fix a forcing notion  $\mathbb{P} \in \mathcal{M}$ , an  $\mathcal{M}$ -generic  $g \subseteq \mathbb{P}$  and an  $\mathcal{N}$ -generic  $h \subseteq \pi(\mathbb{P})$ . Then the following are equivalent:*

- (i)  $\pi[g] \subseteq h$ ;
- (ii) *There exists an elementary  $\pi^+: \mathcal{M}[g] \rightarrow \mathcal{N}[h]$  such that  $\pi^+(g) = h$  and  $\pi^+ \upharpoonright \mathcal{M} = \pi$ .*

**PROOF.** (ii)  $\Rightarrow$  (i) is clear, so assume (i). Define  $\pi^+: \mathcal{M}[g] \rightarrow \mathcal{N}[h]$  as  $\pi^+(\dot{\tau}^g) := \pi(\tau)^h$ . To see that  $\pi^+$  is well-defined fix  $\dot{\sigma}, \dot{\tau} \in \mathcal{M}^{\mathbb{P}}$  such that  $\dot{\sigma}^g = \dot{\tau}^g$ , and fix  $p \in g$  such that  $p \Vdash \dot{\sigma} = \dot{\tau}$ . By elementarity  $\pi(p) \Vdash \pi(\dot{\sigma}) = \pi(\dot{\tau})$ , so since  $\pi(p) \in h$  by (i) we get that  $\pi(\dot{\sigma})^h = \pi(\dot{\tau})^h$ .

To show elementarity, note that for  $x \in \mathcal{M}$  it holds that  $\pi(\check{x}) = \pi(\check{x})$ , implying  $\pi^+(x) = \pi^+(\check{x}^g) = \pi(\check{x})^h = \pi(x)$ . Further, letting  $\dot{g} \in \mathcal{M}^{\mathbb{P}}$  be the standard  $\mathbb{P}$ -

name for  $g$ , then  $\pi(\dot{g})$  is the standard  $\pi(\mathbb{P})$ -name for  $h$  and therefore  $\pi^+(g) = h$ . ■

### 1.5.2 Countable embedding absoluteness

A key folklore lemma which we will frequently need when dealing with elementary embeddings existing in generic extensions is the following:

**LEMMA 1.52** (Countable Embedding Absoluteness). *Let  $\mathcal{M}, \mathcal{N}$  be sets,  $\mathcal{P}$  a transitive class with  $\mathcal{M}, \mathcal{N} \in \mathcal{P}$ , and let  $\pi: \mathcal{M} \rightarrow \mathcal{N}$  be an elementary embedding. Assume that  $\mathcal{P} \models \text{ZF}^- + \text{DC} + \ulcorner \mathcal{M} \text{ is countable} \urcorner$  and fix any finite  $X \subseteq \mathcal{M}$ .*

*Then  $\mathcal{P}$  contains an elementary embedding  $\pi^*: \mathcal{M} \rightarrow \mathcal{N}$  which agrees with  $\pi$  on  $X$ . If  $\pi$  has a critical point and if  $\mathcal{M}$  is transitive then we can also assume that  $\text{crit } \pi = \text{crit } \pi^*$ .<sup>16</sup>*

**PROOF.** Let  $\{a_i \mid i < \omega\} \in \mathcal{P}$  be an enumeration of  $\mathcal{M}$  and set

$$\mathcal{M} \upharpoonright n := \{a_i \mid i < n\}.$$

Then, in  $\mathcal{P}$ , build the tree  $\mathcal{T}$  of all partial isomorphisms between  $\mathcal{M} \upharpoonright n$  and  $\mathcal{N}$  for  $n < \omega$ , agreeing with  $\pi$  on  $X$ , ordered by extension. Then  $\mathcal{T}$  is illfounded in  $V$  by assumption, so it is also illfounded in  $\mathcal{P}$  since  $\mathcal{P}$  is transitive and  $\mathcal{P} \models \text{ZF}^- + \text{DC}$ . The branch then gives us the embedding  $\pi^*$ , and if  $\text{crit } \pi$  exists then we can ensure that it agrees with  $\pi$  on the critical point and finitely many values by adding these conditions to  $\mathcal{T}$ . ■

The following proposition is an almost immediate corollary of Countable Embedding Absoluteness:

**PROPOSITION 1.53.** *Let  $\mathcal{M}$  and  $\mathcal{N}$  be transitive models and assume that there is a generic elementary embedding  $\pi: \mathcal{M} \rightarrow \mathcal{N}$ . Then  $V^{\text{Col}(\omega, \mathcal{M})}$  has an elementary embedding  $\pi^*: \mathcal{M} \rightarrow \mathcal{N}$  which agrees with  $\pi$  on any desired finite set and has the same critical point if it exists.* ■

<sup>16</sup>We are using transitivity of  $\mathcal{M}$  to ensure that the *ordinal*  $\text{crit } \pi$  exists.

### 1.5.3 Preservation of sequence closure

The following lemma is from [Lücke and Schlicht, 2014] and gives a useful condition on when sequence closure is preserved when moving to generic extensions:

**LEMMA 1.54.** *Let  $\lambda$  be an infinite cardinal,  $\mathcal{M} \models ZF^-$  a transitive model,  $\mathbb{P} \in \mathcal{M}$  a  $\lambda^+$ -cc forcing notion and  $g \subseteq \mathbb{P}$  an  $\mathcal{M}$ -generic filter. Then  $V \models {}^\lambda \mathcal{M} \subseteq \mathcal{M}$  implies that  $V[g] \models {}^\lambda \mathcal{M} \subseteq \mathcal{M}$ .*

**PROOF.** Work in  $V[g]$ . Let  $c := \langle c_\alpha \mid \alpha < \lambda \rangle$  be a  $\lambda$ -sequence such that  $c_\alpha \in \mathcal{M}[g]$  for every  $\alpha < \lambda$ . Fix for every  $\alpha < \lambda$  a  $\mathbb{P}$ -name  $\dot{c}_\alpha$  such that  $\dot{c}_\alpha^g = c_\alpha$ . Also let  $\dot{a}$  be a  $\mathbb{P}$ -name with  $\dot{a}^g = \langle \dot{c}_\alpha \mid \alpha < \lambda \rangle$  and choose  $p \in g$  such that  $V \models \ulcorner p \Vdash \forall \alpha < \check{\lambda}: \dot{a}(\alpha) \in \mathcal{M}^{\mathbb{P}} \urcorner$ .

Now, working in  $V$ , there is for each  $\alpha < \lambda$  a maximal antichain  $A_\alpha$  below  $p$  such that every  $q \in A_\alpha$  decides  $\dot{a}(\alpha)$ ; i.e.,  $q \Vdash \dot{a}(\alpha) = \check{x}$  for some  $x \in \mathcal{M}$ . Define now

$$\sigma := \{((\alpha, x), q) \mid \alpha < \lambda \wedge q \in A_\alpha \wedge q \Vdash \dot{a}(\alpha) = \check{x}\}.$$

Then  $p \Vdash \sigma = \dot{a}$ . Note that  $|\sigma| \leq \lambda$ , since  $|A_\alpha| \leq \lambda$  for each  $\alpha < \lambda$ . Thus  $\sigma \in \mathcal{M}$ . Now it holds that

$$V[g] \models \ulcorner \langle \dot{c}_\alpha \mid \alpha < \lambda \rangle = \dot{a}^g = \sigma^g \in \mathcal{M}[g] \urcorner,$$

and we can compute  $c = \langle c_\alpha \mid \alpha < \lambda \rangle = \langle \dot{c}_\alpha^g \mid \alpha < \lambda \rangle$  from  $\langle \dot{c}_\alpha \mid \alpha < \lambda \rangle$  and  $g$ , so  $c \in \mathcal{M}[g]$  by Replacement. ■

## 2 | VIRTUAL LARGE CARDINALS

In this chapter we investigate the properties of virtual versions of well-known large cardinals, including measurables, strongs, supercompacts, Woodins and Vopěnkas. This entails firstly analysing the relationships between them, and secondly looking at more general properties in terms of their behaviour in core models as well as their indestructibility. This virtual perspective also allows us to analyse virtualised versions of large cardinals that are otherwise inconsistent with ZFC, such as the Berkeley cardinals.

### 2.1 STRONGS & SUPERCOMPACTS

We start out with measurables, strongs and supercompacts. Their (non-virtual) definitions can be found in Section 1.3.

**DEFINITION 2.1.** For  $\theta$  a regular uncountable cardinal, a cardinal  $\kappa < \theta$  is...

- **faintly  $\theta$ -measurable** if, in a forcing extension of  $V$ , there is a transitive set  $\mathcal{N}$  and an elementary embedding  $\pi: H_\theta^V \rightarrow \mathcal{N}$  with  $\text{crit } \pi = \kappa$ ;
- **faintly  $\theta$ -strong** if, in a forcing extension of  $V$ , there is a transitive set  $\mathcal{N}$  with  $H_\theta^V \subseteq \mathcal{N}$  and an elementary embedding  $\pi: H_\theta^V \rightarrow \mathcal{N}$  with  $\text{crit } \pi = \kappa$ ;
- **faintly  $\theta$ -supercompact** if, in a forcing extension of  $V$ , there is a transitive set  $\mathcal{N}$  with  ${}^{<\theta}\mathcal{N} \cap V \subseteq \mathcal{N}$  and an elementary embedding  $\pi: H_\theta^V \rightarrow \mathcal{N}$  with  $\text{crit } \pi = \kappa$ .

We further replace “faintly” by **virtually** when  $\mathcal{N} \subseteq V$ , we attach a “**pre**” if we do not assume that  $\pi(\kappa) > \theta$ , and we will leave out  $\theta$  when it holds for all regular  $\theta > \kappa$ . ◦

As a quick example of this terminology, a *faintly prestrong cardinal* is a cardinal  $\kappa$  such that for all regular  $\theta > \kappa$ ,  $\kappa$  is faintly  $\theta$ -measurable with  $H_\theta^V \subseteq \mathcal{N}$ .

Observe that whenever we have a virtual large cardinal that has its defining property for all regular  $\theta$ , we can assume that the target of the embedding is an *element* of the ground model  $V$  and not just a subset of  $V$ . Suppose, for instance,

that  $\kappa$  is virtually measurable and fix a regular  $\theta > \kappa$  and set  $\lambda := (2^{<\theta})^+$ . Take a generic elementary embedding  $\pi : H_\lambda \rightarrow \mathcal{M}_\lambda$  witnessing that  $\kappa$  is virtually  $\lambda$ -measurable.

Since  $|H_\theta| = 2^{<\theta}$  it holds that  $H_\theta \in H_\lambda$ , so that the restriction  $\pi \upharpoonright H_\theta : H_\theta \rightarrow \pi(H_\theta)$  witnesses that  $\kappa$  is virtually  $\theta$ -measurable, and the target model  $\mathcal{M}_\theta := \pi(H_\theta)$  is in  $V$  because  $\mathcal{M}_\lambda \subseteq V$  by assumption. Thus, the weaker assumption that the target model is a subset of the ground model only affects level-by-level virtual large cardinals. Indeed, as we will see in later sections, for virtually strong cardinals we may even further weaken the assumption that  $\mathcal{M}_\theta \subseteq V$  to  $H_\theta = H_\theta^{\mathcal{M}_\theta}$  (we do not know whether this holds level-by-level).

We note that even small cardinals can be faintly measurable: we may for instance have a precipitous ideal on  $\omega_1$ ; see [Jech, 2006, Theorem 22.33]. The “virtually” adverb further implies that the cardinals are large cardinals in the usual sense, as Proposition 2.2 below shows.

**PROPOSITION 2.2** (Virtualised folklore). *For any regular uncountable cardinal  $\theta$ , every virtually  $\theta$ -measurable cardinal is 1-iterable<sup>1</sup> (in particular, inaccessible).*

**PROOF.** Let  $\kappa$  be virtually  $\theta$ -measurable, witnessed by a forcing  $\mathbb{P}$ , a transitive  $\mathcal{N} \subseteq V$  and an elementary  $\pi : H_\theta^V \rightarrow \mathcal{N}$  with  $\pi \in V^\mathbb{P}$ . If  $\kappa$  is not a strong limit then we have a surjection  $\pi(f) : \mathcal{P}(\alpha) \rightarrow \pi(\kappa)$  with  $\text{ran } \pi(f) = \text{ran } f \subseteq \kappa$  for some  $\alpha < \kappa$ ,  $\not\subseteq$ . Note that we used  $\mathcal{N} \subseteq V$  to ensure that  $\mathcal{P}(\alpha)^V = \mathcal{P}(\alpha)^\mathcal{N}$ . The same argument shows that  $\kappa$  is regular. By restricting the generic embedding and using that  $\mathcal{P}(\kappa)^V = \mathcal{P}(\kappa)^\mathcal{N}$  as  $\mathcal{N} \subseteq V$  and  $\mathcal{P}(\kappa)^V \subseteq \mathcal{N}$ , we get that  $\kappa$  is 1-iterable. ■

Along with the above definition of faint supercompactness we can also virtualise Magidor’s characterisation of supercompact cardinals<sup>2</sup>, which was one of the original characterisations of the remarkable cardinals in [Schindler, 2000a].

<sup>1</sup>See Section 1.3 for a definition of the 1-iterable cardinals.

<sup>2</sup>See Section 1.3 for a definition of the non-virtual version of this characterisation.

**DEFINITION 2.3.** Let  $\theta$  be a regular uncountable cardinal. Then  $\kappa < \theta$  is **virtually  $\theta$ -Magidor-supercompact** if there are cardinals  $\bar{\theta} < \kappa$  and  $\bar{\kappa} < \bar{\theta}$ , and a generic elementary  $\pi: H_{\bar{\theta}}^V \rightarrow H_{\theta}^V$  such that  $\text{crit } \pi = \bar{\kappa}$  and  $\pi(\bar{\kappa}) = \kappa$ .  $\circ$

[Gitman and Schindler, 2018] observed that remarkable cardinals are precisely the virtually supercompacts. Surprisingly, they are also precisely the virtually strongs, which in turn makes virtually strongs and virtually supercompacts equivalent. The proofs of these equivalences were omitted in [Gitman and Schindler, 2018], so we give proofs of these here. These are not the original proofs, however, but a slight improvement that allows us to get a more fine-grained level-wise corollary – see Remark 2.5.

**THEOREM 2.4** ([Gitman and Schindler, 2018]). *For an uncountable cardinal  $\kappa$ , the following are equivalent:*

- (i)  $\kappa$  is virtually strong;
- (ii)  $\kappa$  is virtually supercompact;
- (iii)  $\kappa$  is virtually Magidor-supercompact.

**PROOF.** (ii)  $\Rightarrow$  (i) is simply by definition.

(i)  $\Rightarrow$  (iii): Fix  $\theta > \kappa$ . By (i) there exists a generic elementary embedding  $\pi: H_{(2^{<\theta})^+}^V \rightarrow \mathcal{M}$  with<sup>3</sup>  $\text{crit } \pi = \kappa$ ,  $\pi(\kappa) > \theta$ ,  $H_{(2^{<\theta})^+}^V \subseteq \mathcal{M}$  and  $\mathcal{M} \subseteq V$ . Since  $H_{\theta}^V, H_{\pi(\theta)}^{\mathcal{M}} \in \mathcal{M}$ , Countable Embedding Absoluteness 1.52 implies that  $\mathcal{M}$  has a generic elementary embedding  $\pi^*: H_{\theta}^V \rightarrow H_{\pi(\theta)}^{\mathcal{M}}$  with  $\text{crit } \pi^* = \kappa$  and  $\pi^*(\kappa) = \pi(\kappa) > \theta$ . Since  $H_{\theta}^V = H_{\theta}^{\mathcal{M}}$  as  $\mathcal{M} \subseteq V$  and  $H_{\theta}^V \subseteq \mathcal{M}$ , elementarity of  $\pi$  now implies that  $H_{(2^{<\theta})^+}^V$  has cardinals  $\bar{\theta} < \kappa$  and  $\bar{\kappa} < \bar{\theta}$ , and a generic elementary  $\sigma: H_{\bar{\theta}}^V \rightarrow H_{\theta}^V$  with  $\text{crit } \sigma = \bar{\kappa}$  and  $\sigma(\bar{\kappa}) = \kappa$ . This shows (iii).

(iii)  $\Rightarrow$  (ii): Fix  $\theta > \kappa$  and set  $\delta := (2^{<\theta})^+$ . By (iii) there exist cardinals  $\bar{\delta} < \kappa$  and  $\bar{\kappa} < \bar{\delta}$ , and a generic elementary embedding  $\pi: H_{\bar{\delta}}^V \rightarrow H_{\delta}^V$  with  $\text{crit } \pi = \bar{\kappa}$  and  $\pi(\bar{\kappa}) = \kappa$ . We will argue that  $\bar{\kappa}$  is virtually  $\bar{\theta}$ -supercompact in  $H_{\bar{\delta}}^V$ , so that by elementarity  $\kappa$  is virtually  $\theta$ -supercompact in  $H_{\delta}^V$  and hence also in  $V$  by the choice of  $\delta$ . Consider the restriction

$$\sigma := \pi \upharpoonright H_{\bar{\theta}}^V: H_{\bar{\theta}}^V \rightarrow H_{\theta}^V.$$

<sup>3</sup>The domain of  $\pi$  is  $H_{(2^{<\theta})^+}^V$  to ensure that  $H_{\theta}^V \in \text{dom } \pi$ .

Note that  $H_\theta^V$  is closed under  $<\bar{\theta}$ -sequences (and more) in  $V$ . Now define

$$X := \bar{\theta}+1 \cup \{x \in H_\theta^V \mid \exists y \in H_\theta^V \exists p \in \text{Col}(\omega, H_\theta^V) : p \Vdash \dot{\sigma}(\dot{y}) = \dot{x}\} \in V.$$

Note that  $|X| = |H_\theta^V| = 2^{<\bar{\theta}}$  and that  $\text{ran } \sigma \subseteq X$ . Now let  $\overline{\mathcal{M}} \prec H_\theta^V$  be such that  $X \subseteq \overline{\mathcal{M}}$  and  $\overline{\mathcal{M}}$  is closed under  $<\bar{\theta}$ -sequences. Note that we can find such an  $\overline{\mathcal{M}}$  of size  $(2^{<\bar{\theta}})^{<\bar{\theta}} = 2^{<\bar{\theta}}$ . Let  $\mathcal{M}$  be the transitive collapse of  $\overline{\mathcal{M}}$ , so that  $\mathcal{M}$  is still closed under  $<\bar{\theta}$ -sequences and we also still have that  $|\mathcal{M}| = 2^{<\bar{\theta}} < \bar{\delta}$ , making  $\mathcal{M} \in H_{\bar{\delta}}^V$ .

Countable Embedding Absoluteness 1.52 then implies that  $H_{\bar{\delta}}^V$  has a generic elementary embedding  $\sigma^*: H_\theta^V \rightarrow \mathcal{M}$  with  $\text{crit } \sigma^* = \bar{\kappa}$ , showing that  $\bar{\kappa}$  is virtually  $\bar{\theta}$ -supercompact in  $H_{\bar{\delta}}^V$ , which is what we wanted to show. ■

*Remark 2.5.* As mentioned above, the proof in fact shows something stronger: if  $\kappa$  is virtually  $(2^{<\theta})^+$ -strong then it is virtually  $\theta$ -supercompact, and if it is virtually  $(2^{<\theta})^+$ -Magidor-supercompact then it is virtually  $\theta$ -supercompact. It is open whether these notions are equivalent level-by-level (see Question 5.1).

As a corollary of the proof, we obtain the following weaker characterization of virtually strong cardinals:

**PROPOSITION 2.6.** *A cardinal  $\kappa$  is virtually strong if and only if for every  $\theta > \kappa$  there is a forcing extension, in which there is a transitive set  $\mathcal{N}$  and an elementary embedding  $\pi : H_\theta \rightarrow \mathcal{N}$  with  $\text{crit } \pi = \kappa$  and  $H_\theta = H_\theta^{\mathcal{N}}$ .* ■

A key difference between the normal large cardinals and the virtual kinds is that we do not have a virtual version of the Kunen inconsistency<sup>4</sup>: it is perfectly possible to have a generic elementary embedding  $H_\theta^V \rightarrow H_\theta^V$  with  $\theta$  much larger than the critical point, and thus in particular also the image of the critical point. Here is an example of such a virtualised Kunen inconsistency.

---

<sup>4</sup>See Section 1.3 for a definition of the Kunen inconsistency.

**PROPOSITION 2.7** (Folklore). *If  $0^\sharp$  exists then there are inaccessible cardinals  $\kappa < \theta$  such that, in a generic extension of  $L$ , there is an elementary embedding*

$$\pi : L_\theta \rightarrow L_\theta.$$

*In other words,  $\pi$  witnesses a strong failure of the virtualised Kunen inconsistency.*

PROOF. From  $0^\sharp$  we get an elementary embedding  $j : L \rightarrow L$ . Let  $C \subseteq \text{On}$  be the proper class club of limit points of  $j$  above  $\text{crit } j$ , which then contains an  $L$ -inaccessible cardinal  $\theta$  as there are stationarily many such. Restrict  $j$  to  $\pi := j \upharpoonright L_\theta : L_\theta \rightarrow \mathcal{N}$  and note that  $\mathcal{N} = L_\theta$  by condensation of  $L$  and because  $\theta$  is a limit point of  $j$ . Let  $\kappa := \text{crit } \pi$ . Now an application of Countable Embedding Absoluteness 1.52 shows that a generic extension of  $L$  contains an elementary embedding  $\tilde{\pi} : L_\theta \rightarrow L_\theta$  with  $\text{crit } \tilde{\pi} = \kappa$ . ■

This becomes important when dealing with the “pre”-versions of the large cardinals. We next move to a virtualisation of the  $\alpha$ -superstrong cardinals.

**DEFINITION 2.8.** Let  $\theta$  be a regular uncountable cardinal and  $\alpha$  an ordinal. Then a cardinal  $\kappa < \theta$  is **faintly**  $(\theta, \alpha)$ -**superstrong** if it is faintly  $\theta$ -measurable,  $H_\theta^V \subseteq \mathcal{N}$  and  $\pi^\alpha(\kappa) \leq \theta$ .<sup>5</sup> We replace “faintly” by **virtually** when  $\mathcal{N} \subseteq V$ , we say that  $\kappa$  is **faintly**  $\alpha$ -**superstrong** if it is faintly  $(\theta, \alpha)$ -superstrong for *some*  $\theta$ , and  $\kappa$  is simply **faintly superstrong** if it is faintly 1-superstrong.<sup>6</sup> ◻

As in the non-virtual case, the virtually superstrongs surpass the virtually strongs in consistency strength. This then also implies that the superstrongs are stronger than the virtually supercompacts, which is *not* the case outside the virtual world.

**PROPOSITION 2.9** (N.). *If  $\kappa$  is faintly superstrong then  $H_\kappa$  has a proper class of virtually strong cardinals, and thus also a proper class of virtually supercompact cardinals.*

<sup>5</sup>Here  $\pi^1 = \pi$ ,  $\pi^{\alpha+1} = \pi \circ \pi^\alpha$  and  $\pi^\alpha(\kappa) = \sup_{\xi < \alpha} \pi^\xi(\kappa)$  when  $\alpha$  is a limit ordinal.

<sup>6</sup>Note that the conventions stated here are different from the ones in Definition 2.1.

PROOF. Fix a regular  $\theta > \kappa$  and a generic embedding  $\pi: H_\theta^V \rightarrow \mathcal{N}$  with  $\text{crit } \pi = \kappa$ ,  $H_\theta^V \subseteq \mathcal{N}$  and  $\pi(\kappa) \leq \theta$ . Then  $\pi(\kappa)$  is a  $V$ -cardinal, so that  $H_{\pi(\kappa)}^V$  thinks that  $\kappa$  is virtually strong. This implies that  $H_\kappa^V$  thinks there is a proper class of virtually strong cardinals, using that  $H_\kappa^V \prec H_{\pi(\kappa)}^V$ . ■

The following theorem and its subsequent corollaries then show that the only thing stopping prestrongness from being equivalent to strongness is the existence of virtualised Kunen inconsistencies:

**THEOREM 2.10 (N.).** *Let  $\theta$  be an uncountable cardinal. Then a cardinal  $\kappa < \theta$  is virtually  $\theta$ -prestrong iff either*

- (i)  $\kappa$  is virtually  $\theta$ -strong; or
- (ii)  $\kappa$  is virtually  $(\theta, \omega)$ -superstrong.

PROOF.  $(\Leftarrow)$  is trivial, so we show  $(\Rightarrow)$ . Let  $\kappa$  be virtually  $\theta$ -prestrong. Assume (i) fails, meaning that there is a generic elementary embedding  $\pi: H_\theta \rightarrow \mathcal{N}$  for some transitive  $\mathcal{N} \subseteq V$  with  $H_\theta \subseteq \mathcal{N}$ ,  $\text{crit } \pi = \kappa$  and  $\pi(\kappa) \leq \theta$ .

First, assume that there is some  $n < \omega$  such that  $\pi^n(\kappa) = \theta$ . The proof of Proposition 2.9 shows that  $\kappa$  is virtually strong in  $H_{\pi(\kappa)}$ . It follows that  $\pi(\kappa)$  is virtually strong in  $H_{\pi^2(\kappa)}$  by elementarity, and by applying elementarity repeatedly we get that  $\pi^n(\kappa) = \theta$  is virtually strong in  $\mathcal{N}$ . Note that the condition  $\pi^n(\kappa) = \theta$  implies that  $\theta$  is inaccessible in  $\mathcal{N}$ , and hence a limit cardinal there.

In particular,  $\theta$  is virtually  $\delta := (\theta^+)^{\mathcal{N}}$ -strong in  $\mathcal{N}$ , so that  $\mathcal{N}$  has a generic elementary embedding  $\sigma: H_\delta^{\mathcal{N}} \rightarrow \mathcal{M}$  with  $\text{crit } \sigma = \theta$  and  $H_\theta^V \subseteq H_\delta^{\mathcal{N}} \subseteq \mathcal{M}$ . Thus,  $H_\theta^V \prec H_{\sigma(\theta)}^{\mathcal{M}}$ , from which it follows that  $\kappa$  is virtually strong in  $H_{\sigma(\theta)}^{\mathcal{M}}$  and, in particular, virtually  $\theta$ -strong. But  $H_{\sigma(\theta)}^{\mathcal{M}}$  must be correct about this since  $H_\theta^{\mathcal{M}} = H_\theta^{\mathcal{N}} = H_\theta$ , from which we can conclude that  $\kappa$  is actually virtually  $\theta$ -strong, contradicting our assumption that (i) fails.

Next, assume that there is a least  $n < \omega$  such that  $\pi^{n+1}(\kappa) > \theta$ . Since  $\pi(\kappa) \leq \theta$ , we have as before that  $\kappa$  is virtually strong in  $H_{\pi(\kappa)}$ . Since  $H_{\pi^i(\kappa)} \prec H_{\pi^{i+1}(\kappa)}$  holds by elementarity, we have that  $\kappa$  is virtually strong in  $H_{\pi^n(\kappa)}$ . Applying elementarity to the statement that  $\kappa$  is virtually strong in  $H_{\pi(\kappa)}$  we also get that  $\pi^n(\kappa)$  is virtually strong in  $H_{\pi^{n+1}(\kappa)}^{\mathcal{N}}$ .

This means that there is some generic elementary embedding  $\sigma: H_\theta \rightarrow \mathcal{M}$  with  $H_\theta \subseteq \mathcal{M}$ ,  $\mathcal{M} \subseteq H_{\pi^{n+1}(\kappa)}^\mathcal{N}$ ,  $\text{crit } \sigma = \pi^n(\kappa)$  and  $\sigma(\pi^n(\kappa)) > \theta$ . Thus, again by elementarity, we get that  $H_{\pi^n(\kappa)} \prec H_{\sigma(\pi^n(\kappa))}^\mathcal{M}$ . Since, as we already argued,  $\kappa$  is virtually strong in  $H_{\pi^n(\kappa)}$ , this means that  $\kappa$  is also virtually strong in  $H_{\sigma(\pi^n(\kappa))}^\mathcal{M}$  and as  $H_\theta^\mathcal{M} = H_\theta^\mathcal{N} = H_\theta$ , this means that  $\kappa$  is actually virtually  $\theta$ -strong, contradicting our assumption that (i) fails.

Finally, assume  $\pi^n(\kappa) < \theta$  for all  $n < \omega$  and let  $\lambda = \sup_{n < \omega} \pi^n(\kappa)$ . Since  $\lambda \leq \theta$ , we have that  $\kappa$  is virtually  $(\theta, \omega)$ -superstrong by definition. ■

To get a better intuition for the virtual  $\omega$ -superstrongs, recall that a cardinal  $\kappa$  is **virtually rank-into-rank** if there exists a cardinal  $\theta > \kappa$  and a generic elementary embedding  $\pi: H_\theta^V \rightarrow H_\theta^V$  with  $\text{crit } \pi = \kappa$ . We then note that the virtually  $\omega$ -superstrongs coincide with the virtually rank-into-ranks.

**PROPOSITION 2.11 (N.).** *A regular uncountable cardinal  $\kappa$  is virtually  $\omega$ -superstrong iff it is virtually rank-into-rank.*

**PROOF.** If  $\kappa$  is virtually  $\omega$ -superstrong, witnessed by a generic elementary embedding  $\pi: H_\theta^V \rightarrow \mathcal{N}$ , then  $\lambda := \sup_{n < \omega} \pi^n(\kappa)$  is well-defined. By restricting  $\pi$  to  $\pi \upharpoonright H_\lambda^V: H_\lambda^V \rightarrow H_\lambda^V$  we get a witness to  $\kappa$  being virtually  $\lambda$ -rank-into-rank. Conversely, if  $\kappa$  is  $\theta$ -rank-into-rank, witnessed by a generic embedding  $\pi: H_\theta^V \rightarrow H_\theta^V$ , then one readily checks that  $\pi$  also witnesses that  $\kappa$  is virtually  $\omega$ -superstrong. ■

Theorem 2.10 also gives us the following surprising consistency result:

**COROLLARY 2.12 (N.).** *For any uncountable regular  $\theta$ , the existence of a virtually  $\theta$ -strong cardinal is equiconsistent with the existence of a faintly  $\theta$ -measurable cardinal.*

**PROOF.** The above Proposition 2.9 and Theorem 2.10 show that virtually  $\theta$ -prestrongs are equiconsistent with virtually  $\theta$ -strongs. Now note that Countable Embedding Absoluteness 1.52 and condensation in  $L$  imply that every faintly  $\theta$ -measurable cardinal is virtually  $\theta$ -prestrong in  $L$ . ■

## 2.2 WOODINS &amp; VOPĚNKAS

In this section we will analyse the virtualisations of the Woodin and Vopěnka cardinals, which are defined using “boldface” variants of strongs and supercompacts.

**DEFINITION 2.13.** Let  $\theta$  be a regular uncountable cardinal. Then a cardinal  $\kappa < \theta$  is **faintly**  $(\theta, A)$ -**strong** for a set  $A \subseteq H_\theta^V$  if there exists a generic elementary embedding

$$\pi: (H_\theta^V, \in, A) \rightarrow (\mathcal{M}, \in, B)$$

with  $\mathcal{M}$  transitive, such that  $\text{crit } \pi = \kappa$ ,  $\pi(\kappa) > \theta$ ,  $H_\theta^V \subseteq \mathcal{M}$  and  $B \cap H_\theta^V = A$ .  $\kappa$  is **faintly**  $(\theta, A)$ -**supercompact** if we further have that  ${}^{<\theta}\mathcal{M} \cap V \subseteq \mathcal{M}$  and say that  $\kappa$  is **faintly**  $(\theta, A)$ -**extendible** if  $\mathcal{M} = H_\mu^V$  for some  $V$ -cardinal  $\mu$ . We will leave out  $\theta$  if it holds for all regular  $\theta > \kappa$ .  $\circ$

**DEFINITION 2.14.** A cardinal  $\delta$  is **faintly Woodin** if given any  $A \subseteq H_\delta^V$  there exists a faintly  $(<\delta, A)$ -strong cardinal  $\kappa < \delta$ .  $\circ$

As with the previous definitions, for both of the above two definitions we substitute “faintly” for **virtually** when  $\mathcal{M} \subseteq V$ , and substitute “strong”, “supercompact” and “Woodin” for **prestrong**, **presupercompact** and **pre-Woodin** when we do not require that  $\pi(\kappa) > \theta$ .

We note in the following proposition that, in analogy with the real Woodin cardinals, virtually Woodin cardinals are Mahlo. This contrasts the virtually pre-Woodins since [Wilson, 2019a], together with Theorem 2.22 below, show that these can be singular.

**PROPOSITION 2.15** (Virtualised folklore). *Virtually Woodin cardinals are Mahlo.*

**PROOF.** Let  $\delta$  be virtually Woodin. Note that  $\delta$  is a limit of weakly compact cardinals by Proposition 2.2, making  $\delta$  a strong limit. As for regularity, assume that we have a cofinal increasing function  $f: \alpha \rightarrow \delta$  with  $f(0) > \alpha$  and  $\alpha < \delta$ , and note that  $f$  cannot have any closure points since  $f(0) > \alpha$  and  $f$  is increasing. Fix

a virtually  $(<\delta, f)$ -strong cardinal  $\kappa < \delta$ ; we claim that  $\kappa$  is a closure point for  $f$ , which will yield our desired contradiction.

Let  $\gamma < \kappa$  and choose a regular  $\theta \in (\max(f(\gamma), \kappa), \delta)$ . We then have a generic embedding  $\pi: (H_\theta^V, \in, f \cap H_\theta^V) \rightarrow (\mathcal{N}, \in, f^+)$  with  $H_\theta^V \subseteq \mathcal{N}$ ,  $\mathcal{N} \subseteq V$ ,  $\text{crit } \pi = \kappa$ ,  $\pi(\kappa) > \theta$  and  $f^+$  is a function such that  $f^+ \cap H_\theta^V = f \cap H_\theta^V$ . But then  $f^+(\gamma) = f(\gamma) < \pi(\kappa)$  by our choice of  $\theta$ , so elementarity implies that  $f(\gamma) < \kappa$ , making  $\kappa$  a closure point for  $f$ ,  $\nless$ . This shows that  $\delta$  is inaccessible.

As for Mahloness, let  $C \subseteq \delta$  be a club and  $\kappa < \delta$  a virtually  $(<\delta, C)$ -strong cardinal. Let  $\theta \in (\min C, \delta)$  and let  $\pi: H_\theta^V \rightarrow \mathcal{N}$  be the associated generic elementary embedding. Then for every  $\gamma < \kappa$  there exists an element of  $C$  below  $\pi(\kappa)$ , namely  $\min C$ , so by elementarity  $\kappa$  is a limit of elements of  $C$ , making it an element of  $C$ . As  $\kappa$  is regular, this shows that  $\delta$  is Mahlo.  $\blacksquare$

The well-known equivalence of the “function definition” and “ $A$ -strong” definition of Woodin cardinals<sup>7</sup> holds if we restrict ourselves to *virtually* Woodins, and the analogue of the equivalence between virtually strongs and virtually supercompacts allows us to strengthen this:

**PROPOSITION 2.16** (Dimopoulos-Gitman-N.). *For an uncountable cardinal  $\delta$ , the following are equivalent:*

- (i)  $\delta$  is *virtually Woodin*;
- (ii) for every  $A \subseteq H_\delta^V$  there exists a virtually  $(<\delta, A)$ -supercompact  $\kappa < \delta$ ;
- (iii) for every  $A \subseteq H_\delta^V$  there exists a virtually  $(<\delta, A)$ -extendible  $\kappa < \delta$ ;
- (iv) for every function  $f: \delta \rightarrow \delta$  there are regular cardinals  $\kappa < \theta < \delta$ , where  $\kappa$  is a closure point for  $f$ , and a generic elementary  $\pi: H_\theta^V \rightarrow \mathcal{M}$  such that  $\text{crit } \pi = \kappa$ ,  $H_\theta^V \subseteq \mathcal{M}$ ,  $\mathcal{M} \subseteq V$  and  $\theta = \pi(f \upharpoonright \kappa)(\kappa)$ ;
- (v) for every function  $f: \delta \rightarrow \delta$  there are regular cardinals  $\kappa < \theta < \delta$ , where  $\kappa$  is a closure point for  $f$ , and a generic elementary  $\pi: H_\theta^V \rightarrow \mathcal{M}$  such that  $\text{crit } \pi = \kappa$ ,  ${}^{<\pi(f)(\kappa)}\mathcal{M} \subseteq \mathcal{M}$ ,  $\mathcal{M} \subseteq V$  and  $\theta = \pi(f \upharpoonright \kappa)(\kappa)$ ;
- (vi) for every function  $f: \delta \rightarrow \delta$  there are regular cardinals  $\bar{\theta} < \kappa < \theta < \delta$ , where  $\kappa$  is a closure point for  $f$ , and a generic elementary embedding  $\pi: H_{\bar{\theta}}^V \rightarrow H_\theta^V$  with  $\pi(\text{crit } \pi) = \kappa$ ,  $f(\text{crit } \pi) = \bar{\theta}$  and  $f \upharpoonright \kappa \in \text{ran } \pi$ .

<sup>7</sup>See Section 1.3 for this characterisation of (non-virtual) Woodin cardinals.

Figure 2.1: Proof strategy of Proposition 2.16, dotted lines are trivial implications.

PROOF. Firstly note that  $(iii) \Rightarrow (ii) \Rightarrow (i)$  and  $(v) \Rightarrow (iv)$  are simply by definition.

$(i) \Rightarrow (iv)$  Assume  $\delta$  is virtually Woodin, and fix a function  $f: \delta \rightarrow \delta$ . Let  $\kappa < \delta$  be virtually  $(<\delta, f)$ -strong and let  $\theta < \delta$  be a regular cardinal such that  $\sup_{\alpha \leq \kappa} f(\alpha) < \theta$ . Then there is a generic elementary embedding

$$\pi: (H_\theta, \in, f \cap H_\theta) \rightarrow (\mathcal{M}, \in, f^+)$$

such that  $H_\theta \subseteq \mathcal{M}$ ,  $f \cap H_\theta = f^+ \cap H_\theta$ ,  $\mathcal{M} \subseteq V$ , and  $\pi(\kappa) > \theta$ . Note that, by our choice of  $\theta$ ,  $f \upharpoonright \kappa \in H_\theta^V$  and  $\pi(f \upharpoonright \kappa)(\kappa) = f^+(\kappa) = f(\kappa) < \theta$ .

So it suffices to show that  $\kappa$  is a closure point for  $f$ . Let  $\alpha < \kappa$ . Then

$$f(\alpha) = f^+(\alpha) = \pi(f \upharpoonright \kappa)(\alpha) = \pi(f \upharpoonright \kappa)(\pi(\alpha)) = \pi(f(\alpha)),$$

so  $\pi$  fixes  $f(\alpha)$  for every  $\alpha < \kappa$ . Now, if  $\kappa$  was not a closure point of  $f$  then, letting  $\alpha < \kappa$  be the least such that  $f(\alpha) \geq \kappa$ , we have

$$\theta > f(\alpha) = \pi(f(\alpha)) \geq \pi(\kappa) > \theta,$$

a contradiction. Note that we used that  $\pi(\kappa) > \theta$  here, so this argument would not work if we had only assumed  $\delta$  to be virtually pre-Woodin.

$(iv) \Rightarrow (vi)$  Assume  $(iv)$  holds, let  $f: \delta \rightarrow \delta$  be given and define  $g: \delta \rightarrow \delta$  as  $g(\alpha) := (2^{<\gamma_\alpha})^+$ , where  $\gamma_\alpha$  is the least regular cardinal above  $|f(\alpha)|$ . By  $(iv)$  there is a  $\kappa < \delta$  which is a closure point of  $g$  (and so also a closure point of  $f$ ), and there is a regular  $\lambda \in (\kappa, \delta)$  for which there is a generic elementary embedding  $\pi: H_\lambda \rightarrow \mathcal{M}$  with  $\text{crit } \pi = \kappa$ ,  $H_\lambda \subseteq \mathcal{M}$ ,  $\mathcal{M} \subseteq V$ , and  $\pi(g \upharpoonright \kappa)(\kappa) < \lambda$ .

Let  $\theta$  be the least regular cardinal above  $|\pi(f \restriction \kappa)(\kappa)|$ , and note that  $H_\theta \in H_\lambda$  by our definition of  $g$ . Thus, both  $H_\theta$  and  $H_{\pi(\theta)}^\mathcal{M}$  are elements of  $\mathcal{M}$ . An application of Countable Embedding Absoluteness 1.52 then yields that  $\mathcal{M}$  has a generic elementary embedding  $\pi^*: H_\theta^\mathcal{M} \rightarrow H_{\pi(\theta)}^\mathcal{M}$  such that  $\text{crit } \pi^* = \kappa$ ,  $\pi^*(\kappa) = \pi(\kappa)$ ,  $\pi(f \restriction \kappa) \in \text{ran } \pi^*$ , and  $\pi(f \restriction \kappa)(\kappa) < \theta$ . By elementarity of  $\pi$ ,  $H_\theta$  has an ordinal  $\bar{\theta} < \kappa$  and a generic elementary embedding  $\sigma: H_{\bar{\theta}} \rightarrow H_\theta$  with  $\sigma(\text{crit } \sigma) = \kappa$ ,  $f \restriction \kappa \in \text{ran } \sigma$  and  $f(\text{crit } \sigma) < \bar{\theta}$ , which is what we wanted to show.

$(vi) \Rightarrow (v)$  Assume  $(vi)$  holds and let  $f: \delta \rightarrow \delta$  be given. Define  $g: \delta \rightarrow \delta$  as  $g(\alpha) := \langle (2^{<\gamma_\alpha})^+, f(\alpha) \rangle$ , where  $\gamma_\alpha$  is the least regular cardinal above  $|f(\alpha)|$ . In particular,  $g$  codes  $f$ . By  $(vi)$  there exist regular  $\bar{\kappa} < \bar{\lambda} < \kappa < \lambda$  such that  $\kappa$  is a closure point of  $g$  (so also a closure point of  $f$ ) and there exists a generic elementary embedding  $\pi: H_{\bar{\lambda}} \rightarrow H_\lambda$  with  $\text{crit } \pi = \bar{\kappa}$ ,  $\pi(\bar{\kappa}) = \kappa$ ,  $g(\bar{\kappa}) < \bar{\lambda}$ , and  $g \restriction \kappa \in \text{ran } \pi$ . Since  $f$  is definable from  $g$  and  $g \restriction \kappa \in \text{ran } \pi$ , it follows that  $f \restriction \kappa \in \text{ran } \pi$ . So let  $\pi(\bar{f}) = f \restriction \kappa$  with  $\bar{f}: \bar{\kappa} \rightarrow \bar{\kappa}$ . Now observe that  $\bar{f} = f \restriction \bar{\kappa}$  since for  $\alpha < \bar{\kappa}$ , we have  $f(\alpha) = \pi(\bar{f})(\alpha) = \pi(\bar{f}(\alpha)) = \bar{f}(\alpha)$ .

Let  $\bar{\theta}$  be the least regular cardinal above  $|f(\bar{\kappa})|$ . By the definition of  $g$ , we have  $H_{\bar{\theta}} \in H_{\bar{\lambda}}$ . Now, following the  $(iii) \Rightarrow (ii)$  direction in the proof of Theorem 2.4 we get that  $H_{\bar{\lambda}}$  has a generic elementary embedding  $\sigma: H_{\bar{\theta}} \rightarrow \mathcal{M}$  with  $\mathcal{M}$  closed under  $<\bar{\theta}$ -sequences from  $V$ ,  $\text{crit } \sigma = \bar{\kappa}$ ,  $\sigma(\bar{\kappa}) > \bar{\theta}$ , and  $\sigma(\bar{f})(\bar{\kappa}) < \bar{\theta}$ . Let  $\pi(\bar{\theta}) = \theta$  and  $\pi(\mathcal{M}) = \mathcal{N}$ . Now by elementarity of  $\pi$ , we get that there is a generic elementary embedding  $\sigma^*: H_\theta \rightarrow \mathcal{N}$  with  $\text{crit } \sigma^* = \kappa$ ,  $\sigma^*(\kappa) > \theta$ , and  $\sigma^*(\pi(\bar{f}))(\kappa) = \sigma^*(f \restriction \kappa)(\kappa) < \theta$ .

$(vi) \Rightarrow (iii)$  Let  $C$  be the club of all  $\alpha$  such that

$$(H_\alpha, \in, A \cap H_\alpha) \prec (H_\delta, \in, A).$$

Let  $f: \delta \rightarrow \delta$  be given as  $f(\alpha) := \langle \gamma_0^\alpha, \gamma_1^\alpha \rangle$ , where  $\gamma_0^\alpha$  is the first limit point of  $C$  above  $\alpha$  and the  $\gamma_1^\alpha$  are chosen such that  $\{\gamma_1^\alpha \mid \alpha < \beta\}$  encodes  $A \cap \beta$  for cardinals  $\beta$ . This definition makes sense since  $\delta$  is inaccessible by Proposition 2.2.

Let  $\kappa < \delta$  be a closure point of  $f$  such that there are regular cardinals  $\bar{\theta} < \kappa < \theta$  and a generic elementary embedding  $\pi: H_{\bar{\theta}} \rightarrow H_\theta$  such that  $\pi(\text{crit } \pi) = \kappa$ ,  $f(\text{crit } \pi) < \bar{\theta}$ , and  $f \restriction \kappa \in \text{ran } \pi$ . Let  $\bar{\kappa} = \text{crit } \pi$ . We claim that  $\bar{\kappa}$  is virtually  $(<\delta, A)$ -extendible. Since  $\kappa \in C$  because it is a closure point of  $f$ , it suffices by the

definition of  $C$  to show that

$$(H_{\kappa}, \in, A \cap H_{\kappa}) \models \ulcorner \bar{\kappa} \text{ is virtually } (A \cap H_{\kappa})\text{-extendible} \urcorner. \quad (1)$$

Let  $\beta$  be the least element of  $C$  above  $\bar{\kappa}$  but below  $\bar{\theta}$ , and note that  $\beta$  exists as  $f(\bar{\kappa}) < \bar{\theta}$ , and the definition of  $f$  says that the first coordinate of  $f(\bar{\kappa})$  is a limit point of  $C$  above  $\bar{\kappa}$ . It then holds that

$$(H_{\bar{\kappa}}, \in, A \cap H_{\bar{\kappa}}) \prec (H_{\beta}, \in, A \cap H_{\beta})$$

as both  $\bar{\kappa}$  and  $\beta$  are elements of  $C$ . Since  $f$  encodes  $A$  in the manner previously described and  $\pi(f \upharpoonright \bar{\kappa}) = f \upharpoonright \kappa$ , we get that  $\pi(A \cap H_{\bar{\kappa}}) = A \cap H_{\kappa}$ , and thus

$$(H_{\kappa}, \in, A \cap H_{\kappa}) \prec (H_{\pi(\beta)}, \in, A^*) \quad (2)$$

for  $A^* := \pi(A \cap H_{\beta})$ . Now, as  $(H_{\gamma}, \in, A \cap H_{\gamma})$  and  $(H_{\pi(\gamma)}, \in, A^* \cap H_{\pi(\gamma)})$  are elements of  $H_{\pi(\beta)}$  for every  $\gamma < \kappa$ , Countable Embedding Absoluteness 1.52 implies that  $H_{\pi(\beta)}$  sees that  $\bar{\kappa}$  is virtually  $(<\kappa, A^*)$ -extendible, which by (2) then implies (1), which is what we wanted to show. ■

As a corollary of the proof, we now have an analogue of Proposition 2.6 for virtually Woodin cardinals.

**PROPOSITION 2.17** (Dimopoulos-Gitman-N.). *A cardinal  $\delta$  is virtually Woodin if and only if, for every  $A \subseteq H_{\delta}$ , there is a cardinal  $\kappa$  satisfying the weakening of virtual  $(<\delta, A)$ -strongness where  $H_{\theta} = H_{\theta}^{\mathcal{N}}$  holds in place of  $\mathcal{N} \subseteq V$ , with  $\mathcal{N}$  being the target of the generic embedding.* ■

As a corollary we arrive at the surprising result that there is no distinction between the faint and virtual Woodin cardinals, in contrast with what we will see in Theorem 2.50.

**COROLLARY 2.18** (Gitman-N.). *Faintly Woodin cardinals are virtually Woodin.*

PROOF. Using Proposition 2.17, it suffices to observe that if  $\theta$  is inaccessible and

$$\pi : (H_\theta, \in, A) \rightarrow (\mathcal{M}, \in, B)$$

is a faintly  $(\theta, A)$ -strong embedding such that  $A$  codes the sequence of  $H_\lambda$  for  $\lambda < \theta$ , then  $H_\theta = H_\theta^{\mathcal{M}}$ . ■

We will now step away from the Woodins for a little bit, and introduce the Vopěnkas. In anticipation of the next section we will work with the class-sized version here, but all the following results work equally well for inaccessible virtually Vopěnkas cardinals<sup>8</sup>.

**DEFINITION 2.19 (GBC).** The **Generic Vopěnkas Principle (gVP)** states that for any class  $C$  consisting of structures in a common first-order language, there are distinct  $\mathcal{M}, \mathcal{N} \in C$  and a generic elementary embedding  $\pi : \mathcal{M} \rightarrow \mathcal{N}$ . ◦

We will be using a standard variation of gVP involving the following *natural sequences*:

**DEFINITION 2.20 (GBC).** Say that a class function  $f : \text{On} \rightarrow \text{On}$  is an **indexing function** if it satisfies that  $f(\alpha) > \alpha$  and  $f(\alpha) \leq f(\beta)$  for all  $\alpha < \beta$ . ◦

**DEFINITION 2.21 (GBC).** Say that an On-sequence  $\langle \mathcal{M}_\alpha \mid \alpha < \text{On} \rangle$  is **natural** if there exists an indexing function  $f : \text{On} \rightarrow \text{On}$  and unary relations  $R_\alpha \subseteq V_{f(\alpha)}$  such that  $\mathcal{M}_\alpha = (V_{f(\alpha)}, \in, \{\alpha\}, R_\alpha)$  for every  $\alpha$ . Denote this indexing function by  $f^{\vec{\mathcal{M}}}$  and the unary relations as  $R_\alpha^{\vec{\mathcal{M}}}$ . ◦

The following Theorem 2.22 is then the main theorem of this section, showing that inaccessible cardinals are virtually Vopěnkas iff they are virtually pre-Woodin.

**THEOREM 2.22 (Dimopoulos-Gitman-N.; GBC).** *The following are equivalent:*

- (i) *gVP holds;*

---

<sup>8</sup>Note however that we have to require inaccessibility here: see [Wilson, 2019a] for an analysis of the singular virtually Vopěnkas cardinals.

- (ii) For any natural On-sequence  $\vec{\mathcal{M}}$  there exists a generic elementary embedding  $\pi: \mathcal{M}_\alpha \rightarrow \mathcal{M}_\beta$  for some  $\alpha < \beta$ ;
- (iii) On is virtually pre-Woodin;
- (iv) On is faintly pre-Woodin.

PROOF. (i)  $\Rightarrow$  (ii) and (iii)  $\Rightarrow$  (iv) are trivial.

(iv)  $\Rightarrow$  (i): Assume On is faintly pre-Woodin and fix some On-sequence  $\vec{\mathcal{M}} := \langle \mathcal{M}_\alpha \mid \alpha < \text{On} \rangle$  of structures in a common language. Let  $\kappa$  be  $(< \text{On}, \vec{\mathcal{M}})$ -prestrong and fix some regular  $\theta > \kappa$  satisfying that  $\mathcal{M}_\alpha \in H_\theta^V$  for every  $\alpha < \theta$ , and fix a generic elementary embedding

$$\pi: (H_\theta^V, \in, \vec{\mathcal{M}}) \rightarrow (\mathcal{N}, \in, \mathcal{M}^*)$$

with  $H_\theta^V \subseteq \mathcal{N}$  and  $\vec{\mathcal{M}} \cap H_\theta^V = \mathcal{M}^* \cap H_\theta^V$ . Set  $\kappa := \text{crit } \pi$ .

We have that  $\pi \restriction \mathcal{M}_\kappa: \mathcal{M}_\kappa \rightarrow \mathcal{M}_{\pi(\kappa)}^*$ , but we need to reflect this embedding down below  $\theta$  as we do not know whether  $\mathcal{M}_{\pi(\kappa)}^*$  is on the  $\vec{\mathcal{M}}$  sequence. Working in the generic extension, we have

$$\mathcal{N} \models \exists \bar{\kappa} < \pi(\kappa) \exists \dot{\sigma} \in V^{\text{Col}(\omega, \mathcal{M}_{\bar{\kappa}}^*)}: \Vdash \dot{\sigma}: \mathcal{M}_{\bar{\kappa}}^* \rightarrow \mathcal{M}_{\pi(\kappa)}^* \text{ is elementary}^\top.$$

Here  $\kappa$  realises  $\bar{\kappa}$  and  $\pi \restriction \mathcal{M}_\kappa$  realises  $\sigma$ . Note that  $\mathcal{M}_\kappa^* = \mathcal{M}_\kappa$  since we ensured that  $\mathcal{M}_\kappa \in H_\theta^V$  and we are assuming that  $\vec{\mathcal{M}} \cap H_\theta^V = \mathcal{M}^* \cap H_\theta^V$ , so the domain of  $\sigma (= \pi \restriction \mathcal{M}_\kappa)$  is  $\mathcal{M}_\kappa^*$  – also note that  $\sigma$  exists in a  $\text{Col}(\omega, \mathcal{M}_\kappa)$  extension of  $\mathcal{N}$  by an application of Countable Embedding Absoluteness 1.52. Now elementarity of  $\pi$  implies that

$$H_\theta^V \models \exists \bar{\kappa} < \kappa \exists \dot{\sigma} \in V^{\text{Col}(\omega, \mathcal{M}_{\bar{\kappa}})}: \Vdash \dot{\sigma}: \mathcal{M}_{\bar{\kappa}} \rightarrow \mathcal{M}_\kappa \text{ is elementary}^\top,$$

which is upwards absolute to  $V$ , from which we can conclude that  $\sigma: \mathcal{M}_{\bar{\kappa}} \rightarrow \mathcal{M}_\kappa$  witnesses that gVP holds.

(ii)  $\Rightarrow$  (iii): Assume (ii) holds and assume that On is not virtually pre-Woodin, which means that there exists some class  $A$  such that there are no virtually  $A$ -prestrong cardinals. This allows us to define a function  $f: \text{On} \rightarrow \text{On}$  as  $f(\alpha)$  being the least regular  $\eta > \alpha$  such that  $\alpha$  is not virtually  $(\eta, A)$ -prestrong.

We also define  $g: \text{On} \rightarrow \text{On}$  as taking  $\alpha$  to the least strong limit cardinal above  $\alpha$  which is a closure point for  $f$ . Note that  $g$  is an indexing function, so we can let  $\vec{\mathcal{M}}$  be the natural sequence induced by  $g$  and  $R_\alpha := A \cap H_{g(\alpha)}^V$ . (ii) supplies us with  $\alpha < \beta$  and a generic elementary embedding<sup>9</sup>

$$\pi: (H_{g(\alpha)}^V, \in, A \cap H_{g(\alpha)}^V) \rightarrow (H_{g(\beta)}^V, \in, A \cap H_{g(\beta)}^V).$$

Since  $g(\alpha)$  is a closure point for  $f$  it holds that  $f(\text{crit } \pi) < g(\alpha)$ , so fixing a regular  $\theta \in (f(\text{crit } \pi), g(\alpha))$  we get that  $\text{crit } \pi$  is virtually  $(\theta, A)$ -prestrong, contradicting the definition of  $f$ . Hence  $\text{On}$  is virtually pre-Woodin. ■

### 2.2.1 Weak Vopěnka

We now move to a *weak* variant of  $\text{gVP}$ , introduced in a category-theoretic context in [Adámek and Rosický, 1994]. It starts with the following equivalent characterisation of  $\text{gVP}$ , which is the virtual analogue of the characterisation shown in [Adámek and Rosický, 1994]:

**LEMMA 2.23** (Virtualised Adámek-Rosický; GBC). *The following are equivalent<sup>10</sup>:*

- (i)  $\text{gVP}$
- (ii) *There is not a natural On-sequence  $\langle \mathcal{M}_\alpha \mid \alpha < \text{On} \rangle$  satisfying that*
  - *there is a generic homomorphism  $\mathcal{M}_\alpha \rightarrow \mathcal{M}_\beta$  for every  $\alpha \leq \beta$ , which is unique in all generic extensions;*
  - *there is no generic homomorphism  $\mathcal{M}_\beta \rightarrow \mathcal{M}_\alpha$  for any  $\alpha < \beta$ .*
- (iii) *There is not a natural On-sequence  $\langle \mathcal{M}_\alpha \mid \alpha < \text{On} \rangle$  satisfying that*
  - *there is a homomorphism  $\mathcal{M}_\alpha \rightarrow \mathcal{M}_\beta$  in  $V$  for every  $\alpha \leq \beta$ , which is unique in all generic extensions;*
  - *there is no generic homomorphism  $\mathcal{M}_\beta \rightarrow \mathcal{M}_\alpha$  for any  $\alpha < \beta$ .*

**PROOF.** Note that the only difference between (ii) and (iii) is that the homomorphism exists in  $V$ , making (ii)  $\Rightarrow$  (iii) trivial.

<sup>9</sup>Note that  $V_{g(\alpha)} = H_{g(\alpha)}^V$  since  $g(\alpha)$  is a strong limit cardinal.

<sup>10</sup>This is equivalent to saying that  $\text{On}$ , viewed as a category, cannot be fully embedded into the category  $\mathbf{Gra}$  of graphs, which is how it is stated in [Adámek and Rosický, 1994].

(iii)  $\Rightarrow$  (i): Assume that gVP fails, meaning by Theorem 2.22 that we have a natural On-sequence  $\vec{\mathcal{M}}_\alpha$  such that, in every generic extension, there is no homomorphism between any two distinct  $\mathcal{M}_\alpha$ 's. Define  $\langle \mathcal{N}_\kappa \mid \kappa \in \text{Card} \rangle$  as<sup>11</sup>

$$\mathcal{N}_\kappa := \coprod_{\xi \leq \kappa} \mathcal{M}_\xi := \{(x, \xi) \mid \xi \leq \kappa \wedge \xi \in \text{Card} \wedge x \in \mathcal{M}_\xi\},$$

with a unary relation  $R^*$  given as  $R^*(x, \xi)$  iff  $\mathcal{M}_\xi \models R(x)$  and a binary relation  $\sim^*$  given as  $(x, \xi) \sim^* (x', \xi')$  iff  $\xi = \xi'$ . Whenever we have a homomorphism  $f: \mathcal{N}_\kappa \rightarrow \mathcal{N}_\lambda$  we then get an induced homomorphism  $\tilde{f}: \mathcal{M}_0 \rightarrow \mathcal{M}_\xi$ , given as  $\tilde{f}(x) := f(x, 0)$ , where  $\xi \leq \kappa$  is given by preservation of  $\sim^*$ .

For any two cardinals  $\kappa < \lambda$  we have a homomorphism  $j_{\kappa\lambda}: \mathcal{N}_\kappa \rightarrow \mathcal{N}_\lambda$  in  $V$ , given as  $j_{\kappa\lambda}(x, \xi) := (x, \xi)$ . This embedding must also be the *unique* such, in all generic extensions, as otherwise we get a generic homomorphism between two distinct  $\mathcal{M}_\alpha$ 's. Furthermore, there cannot be any homomorphism  $\mathcal{N}_\lambda \rightarrow \mathcal{N}_\kappa$  as that would also imply the existence of a generic homomorphism between two distinct  $\mathcal{M}_\alpha$ 's.

(i)  $\Rightarrow$  (ii): Assume that we have an On-sequence  $\vec{\mathcal{M}}_\alpha$  as in the theorem, with generic homomorphisms  $j_{\alpha\beta}: \mathcal{M}_\alpha \rightarrow \mathcal{M}_\beta$  that are unique in all generic extensions for every  $\alpha \leq \beta$ , with no generic homomorphisms going the other way.

We first note that we can for every  $\alpha \leq \beta$  choose the  $j_{\alpha\beta}$  in a  $\text{Col}(\omega, \mathcal{M}_\alpha)$ -extension, by a proof similar to the proof of Lemma 1.52 and using the uniqueness of  $j_{\alpha\beta}$ . Next, fix a proper class  $C \subseteq \text{On}$  such that  $\alpha \in C$  implies that

$$\sup_{\xi \in C \cap \alpha} |\mathcal{M}_\xi|^V < |\mathcal{M}_\alpha|^V.$$

and note that this implies that  $V[g] \models |\mathcal{M}_\xi| < |\mathcal{M}_\alpha|$  for every  $V$ -generic  $g \subseteq \text{Col}(\omega, \mathcal{M}_\xi)$ . This means that for every  $\alpha \in C$  we may choose some  $\eta_\alpha \in \mathcal{M}_\alpha$  which is *not* in the range of any  $j_{\xi\alpha}$  for  $\xi < \alpha$ . But now define first-order structures  $\langle \mathcal{N}_\alpha \mid \alpha \in C \rangle$  as  $\mathcal{N}_\alpha := (\mathcal{M}_\alpha, \eta_\alpha)$ . Then, by our assumption on the  $\mathcal{M}_\alpha$ 's and construction of the  $\mathcal{N}_\alpha$ 's, there can be no generic homomorphism between any two distinct  $\mathcal{N}_\alpha$ , showing that gVP fails. ■

<sup>11</sup>  $\coprod$  is the “model-theoretic union”, also known as the coproduct.

The *weak* version of gVP is then simply “flipping the arrows around” in the above characterisation of gVP.

**DEFINITION 2.24 (GBC).** **Generic Weak Vopěnkas’s Principle (gWVP)** states that there does *not* exist an On-sequence of first-order structures  $\langle \mathcal{M}_\alpha \mid \alpha < \text{On} \rangle$  such that

- there is a homomorphism  $\mathcal{M}_\beta \rightarrow \mathcal{M}_\alpha$  in  $V$  for every  $\alpha \leq \beta$ , which is unique in all generic extensions;
- there is *no* generic homomorphism  $\mathcal{M}_\alpha \rightarrow \mathcal{M}_\beta$  for any  $\alpha < \beta$ . ◦

We start by showing that gWVP is indeed a weaker version of gVP.

**PROPOSITION 2.25.** *gVP implies gWVP.*

**PROOF.** Assume gVP holds and gWVP fails, and let  $\langle \mathcal{M}_\alpha \mid \alpha < \text{On} \rangle$  be an On-sequence of first-order structures such that for every  $\alpha \leq \beta$  there exists a homomorphism

$$j_{\beta\alpha}: \mathcal{M}_\beta \rightarrow \mathcal{M}_\alpha$$

in  $V$  which is unique in all generic extensions, with no generic homomorphisms going the other way. We can then find a proper class  $C \subseteq \text{On}$  such that  $|\mathcal{M}_\alpha|^V < |\mathcal{M}_\beta|^V$  for every  $\alpha < \beta$  in  $C$ . By gVP there are then  $\alpha < \beta$  in  $C$  and a generic homomorphism

$$\pi: \mathcal{M}_\alpha \rightarrow \mathcal{M}_\beta$$

in some  $V[g]$ . Here we may assume, as in the proof of Lemma 2.23, that  $g \subseteq \text{Col}(\omega, \mathcal{M}_\beta)$ . But then  $\pi \circ j_{\beta\alpha} = \text{id}$  by uniqueness of  $j_{\beta\beta} = \text{id}$ , which means that  $j_{\beta\alpha}$  is injective in  $V[g]$  and hence also in  $V$ . But then  $|\mathcal{M}_\beta|^V \leq |\mathcal{M}_\alpha|^V$ , contradicting the definition of  $C$ . ■

Denoting the corresponding non-generic principle by WVP Wilson showed the following surprising result:

**THEOREM 2.26** ([Wilson, 2019b]). *WVP is equivalent to On being a Woodin cardinal.*

Given our Theorem 2.22 we may then suspect that in the virtual world these two continue to be equivalent, which turns out to *almost* be the case. In the proceeding argument we will be roughly following the structure of the argument in [Wilson, 2019b], but we have to diverge from it at several points in which the author is using the fact that they are working with class-sized elementary embeddings.

Indeed, in that paper they establish a correspondence between elementary embeddings and certain homomorphisms, a correspondence we will not achieve here. Proving that the elementary embeddings we *do* get are non-trivial seems to furthermore require extra assumptions on our structures. In any case, let us begin.

Define for every strong limit cardinal  $\lambda$  and  $\Sigma_1$ -formula  $\varphi$  the relations

$$\begin{aligned} R^\varphi &:= \{x \in V \mid (V, \in) \models \varphi[x]\} \\ R_\lambda^\varphi &:= \{x \subseteq H_\lambda^V \mid \exists y \in R^\varphi : y \cap H_\lambda^V = x\} \end{aligned}$$

and given any class  $A$  define the structure

$$\mathcal{P}_{\lambda,A} := (H_{\lambda^+}^V, R_\lambda^\varphi, \{\lambda\}, A \cap H_\lambda^V)_{\varphi \in \Sigma_1}.$$

Say that a homomorphism  $h: \mathcal{P}_{\lambda,A} \rightarrow \mathcal{P}_{\eta,A}$  is **trivial** if

$$h(x) \cap H_\eta^V = x \cap H_\eta^V$$

for every  $x \in H_{\lambda^+}^V$ . Note that  $h$  can only be trivial if  $\eta \leq \lambda$  since  $h(\lambda) = \eta$ .

**LEMMA 2.27** (Gitman-N; GBC). *Let  $\lambda$  be a singular strong limit cardinal,  $\eta$  a strong limit cardinal and  $A \subseteq V$  a class. If there exists a non-trivial generic homomorphism  $h: \mathcal{P}_{\lambda,A} \rightarrow \mathcal{P}_{\eta,A}$  then there is a non-trivial generic elementary embedding  $\pi: (H_{\lambda^+}^V, \in, A \cap H_\lambda^V) \rightarrow (\mathcal{M}, \in, B)$  for some  $\mathcal{M}$  such that, letting  $\nu := \min\{\lambda, \eta\}$ , it holds that  $H_\nu^V = H_\nu^\mathcal{M}$ ,  $A \cap H_\nu^V = B \cap H_\nu^V$  and  $\text{crit } \pi < \nu$ .*

PROOF. Assume that we have a non-trivial homomorphism  $h: \mathcal{P}_{\lambda,A} \rightarrow \mathcal{P}_{\eta,A}$  in a forcing extension  $V[g]$ , define in  $V[g]$  the set

$$\mathcal{M}^* := \{\langle b, f \rangle \mid b \in [H_\nu]^{<\omega} \wedge f \in H_{\lambda^+}^V \wedge f: H_\lambda^V \rightarrow H_\lambda^V\},$$

and define the standard relations  $\in^*$  and  $=^*$  on  $\mathcal{M}^*$  as

$$\begin{aligned} \langle b_0, f_0 \rangle \in^* \langle b_1, f_1 \rangle &\text{ iff } b_0 b_1 \in h(\{xy \in [H_\lambda^V]^{<\omega} \mid f_0(x) \in f_1(y)\}) \\ \langle b_0, f_0 \rangle =^* \langle b_1, f_1 \rangle &\text{ iff } b_0 b_1 \in h(\{xy \in [H_\lambda^V]^{<\omega} \mid f_0(x) = f_1(y)\}) \end{aligned}$$

Let  $\mathcal{M} := \mathcal{M}^* / =^*$ , and also call  $\in^*$  the induced relation on  $\mathcal{M}$ , which is clearly well-defined. We then get a version of Loś' Theorem, using that  $h$  preserves all  $\Sigma_1$ -relations and that  $H_\lambda^V \models \text{ZFC}^-$ .

*Claim 2.28.* For every formula  $\varphi(v_1, \dots, v_n)$  and every  $[b_1, f_1], \dots, [b_n, f_n] \in \mathcal{M}$  the following are equivalent:

- (i)  $(\mathcal{M}, \in^*) \models \varphi[[b_1, f_1], \dots, [b_n, f_n]]$ ;
- (ii)  $b_1 \cdots b_n \in h(\{a_1 \cdots a_n \mid \mathcal{P}_{\lambda,A} \models \varphi[f_1(a_1), \dots, f_n(a_n)]\})$ .

PROOF OF CLAIM. The proof is straightforward, using that  $h$  preserves  $\Sigma_1$ -relations. We prove this by induction on  $\varphi$ . If  $\varphi$  is  $v_i \in v_j$  then we have that

$$\begin{aligned} (\mathcal{M}, \in^*) \models \varphi[[b_1, f_1], \dots, [b_n, f_n]] &\Leftrightarrow \langle b_i, f_i \rangle \in^* \langle b_j, f_j \rangle \\ &\Leftrightarrow b_i b_j \in h(\{a_i a_j \in [H_\lambda^V]^{<\omega} \mid f_i(a_i) \in f_j(a_j)\}) \\ &\Leftrightarrow b_1 \cdots b_n \in h(\{a_1 \cdots a_n \mid f_i(a_i) \in f_j(a_j)\}) \\ &\Leftrightarrow b_1 \cdots b_n \in h(\{a_1 \cdots a_n \mid \mathcal{P}_{\lambda,A} \models \varphi[f_1(a_1), \dots, f_n(a_n)]\}). \end{aligned}$$

The cases where  $\varphi$  is  $\psi \wedge \chi$  or  $\neg\psi$  is straightforward. If  $\varphi$  is  $\exists x\psi$  then

$$\begin{aligned} (\mathcal{M}, \in^*) \models \varphi[[b_1, f_1], \dots, [b_n, f_n]] &\Leftrightarrow \exists \langle b, f \rangle \in \mathcal{M}^*: (\mathcal{M}, \in) \models \psi[\langle b, f \rangle, \langle b_1, f_1 \rangle, \dots, \langle b_n, f_n \rangle] \\ &\Leftrightarrow \exists \langle b, f \rangle \in \mathcal{M}^*: b b_1 \cdots b_n \in h(\{a \vec{a} \mid \mathcal{P}_{\lambda,A} \models \psi[f(a), f_1(a_1), \dots, f_n(a_n)]\}) \\ &\Leftrightarrow b_1 \cdots b_n \in h(\{\vec{a} \mid \mathcal{P}_{\lambda,A} \models \varphi[f_1(a_1), \dots, f_n(a_n)]\}), \end{aligned}$$

finishing the proof.  $\dashv$

Note that we have not shown that  $(\mathcal{M}, \in^*)$  is well-founded, and indeed it might not be. However, the following claim will show that  $(H_\nu^V, \in)$  is isomorphic to a rank-initial segment of  $(\mathcal{M}^*, \in^*)$ , giving well-foundedness up to that point at least. Define the function  $\chi: (H_\nu^V, \in) \rightarrow (\mathcal{M}^*, \in^*)$  as  $\chi(a) := [\langle a \rangle, \text{pr}]$ , where  $\text{pr}(\langle x \rangle) := x$ .

*Claim 2.29.* For every  $[a, f] \in \mathcal{M}$  and  $b \in H_\nu^V$ ,

$$[a, f] \in^* \chi(b) \iff \exists c \in H_\nu^V : [a, f] = \chi(c).$$

PROOF OF CLAIM. We have that

$$\begin{aligned} [a, f] \in^* \chi(b) &= [\langle b \rangle, \text{pr}] \iff a \langle b \rangle \in h(\{x \langle y \rangle \mid f(x) \in y\}) \\ &\iff a \langle b \rangle \in h(\{x \langle y \rangle \mid \exists z \in y : f(x) = z\}) \\ &\iff \exists c \in b : a \langle c \rangle \in h(\{x \langle z \rangle \mid f(x) = z\}) \\ &\iff \exists c \in b : [a, f] = [\langle c \rangle, \text{pr}] = \chi(c), \end{aligned}$$

yielding the wanted.  $\dashv$

This claim implies that by taking the transitive collapse of  $\text{ran } \chi \subseteq \mathcal{M}$  we may assume that  $H_\nu^V = H_\nu^{\mathcal{M}}$ . Now define

$$B := \{[b, f] \in \mathcal{M} \mid b \in h(\{x \in H_\lambda^V \mid f(x) \in A\})\}.$$

and, in  $V[g]$ , let  $\pi: (H_\lambda^V, \in, A \cap H_\lambda^V) \rightarrow (\mathcal{M}, \in, B)$  be given as  $\pi(x) := [\langle x \rangle, c_x]$ .

*Claim 2.30.*  $\pi$  is elementary.

PROOF OF CLAIM. For  $x_1, \dots, x_n \in H_\lambda^V$  it holds that

$$\begin{aligned} (\mathcal{M}, \in^*, B) \models \varphi[\pi(x_1), \dots, \pi(x_n)] &\Leftrightarrow (\mathcal{M}, \in^*) \models \varphi[\pi(x_1), \dots, \pi(x_n)] \\ &\Leftrightarrow \langle \rangle \in h(\{\langle \rangle \mid \mathcal{P}_{\lambda, A} \models \varphi[x_1, \dots, x_n]\}) \\ &\Leftrightarrow (H_{\lambda^+}^V, \in, A \cap H_\lambda^V) \models \varphi[x_1, \dots, x_n] \end{aligned}$$

and we also get that, for every  $x \in H_\lambda^V$ ,

$$x \in A \Leftrightarrow \langle \rangle \in h(\{a \in H_\lambda^V \mid x \in A\}) \Leftrightarrow \pi(x) \in B,$$

which shows elementarity.  $\dashv$

We next need to show that  $B \cap H_\nu^V = A \cap H_\nu^V$ , so let  $x \in H_\nu^V$ . Note that  $x = [\langle x \rangle, \text{pr}]$  by Claim 2.29 and the observation proceeding it, which means that

$$x \in B \Leftrightarrow \langle x \rangle \in h(\{\langle y \rangle \in H_\lambda^V \mid y \in A\}) \Leftrightarrow x \in A.$$

The last thing we need to show is that  $\text{crit } \pi < \nu$ . We start with an analogous result about  $h$ .

*Claim 2.31.* There exists some  $b \in H_\nu^V$  such that  $h(b) \neq b$ .

PROOF OF CLAIM. Assume the claim fails. We now have two cases.

**Case 1:**  $\lambda \geq \eta$

By non-triviality of  $h$  there is an  $x \in \mathcal{P}^V(H_\lambda^V)$  such that  $h(x) \neq x \cap H_\eta^V$ , which means that there exists an  $a \in H_\eta^V$  such that  $a \in h(x) \Leftrightarrow a \notin x$ .

If  $a \in x$  then  $\{a\} = h(\{a\}) \subseteq h(x)$ ,<sup>12</sup> making  $a \in h(x)$ ,  $\nmid$ , so assume instead that  $a \in h(x)$ . Since  $\eta$  is a strong limit cardinal we may fix a cardinal  $\theta < \eta$  such that  $a \in H_\theta^V$  and  $H_\theta^V \in H_\eta^V$ . We then have that<sup>13</sup>

$$\{a\} \subseteq h(x) \cap H_\theta^V = h(x) \cap h(H_\theta^V) = h(x \cap H_\theta^V) = x \cap H_\theta^V,$$

<sup>12</sup>Note that as  $h$  preserves  $\Sigma_1$  formulas it also preserves singletons and boolean operations.

<sup>13</sup>Note that we are using  $\lambda \geq \eta$  here to ensure that  $H_\theta^V \in \text{dom } h$ .

so that  $a \in x$ ,  $\not\prec$ .

**Case 2:**  $\lambda < \eta$

In this case we are assuming that  $h \upharpoonright H_\lambda^V = \text{id}$ , but  $h(\lambda) = \eta > \lambda$ . Since  $\lambda$  is singular we can fix some  $\gamma < \lambda$  and a cofinal function  $f: \gamma \rightarrow \lambda$ . Define the relation

$$R := \{(\alpha, \beta, \bar{\alpha}, \bar{\beta}, g) \mid \ulcorner g \text{ is a cofinal function } g: \alpha \rightarrow \beta^\top \wedge g(\bar{\alpha}) = \bar{\beta}\}.$$

Then  $R(\gamma, \lambda, \alpha, f(\alpha), f)$  holds by assumption for every  $\alpha < \gamma$ , so that  $R$  holds for some  $(\gamma^*, \lambda^*, \alpha^*, f(\alpha)^*, f^*)$  such that

$$\begin{aligned} (\gamma^*, \lambda^*, \alpha^*, f(\alpha)^*, f^*) \cap H_\eta^V &= (h(\gamma), h(\lambda), h(\alpha), h(f(\alpha)), h(f)) \\ &= (\gamma, \eta, \alpha, f(\alpha), h(f)), \end{aligned}$$

using our assumption that  $h$  fixes every  $b \in H_\lambda^V$ . Since  $\gamma$ ,  $\alpha$  and  $f(\alpha)$  are transitive and bounded in  $H_\lambda^V$ , it holds that  $h(\gamma) = \gamma^*$ ,  $h(\alpha) = \alpha^*$  and that  $h(f(\alpha)) = f(\alpha)^*$ . Also, since  $\text{dom}(f^*) = \gamma = \text{dom}(f)$  we must in fact have that  $f^* = h(f)$ . But this means that  $h(f): \gamma \rightarrow \eta$  is cofinal and  $\text{ran}(h(f)) \subseteq \lambda$ , a contradiction!  $\dashv$

To use the above Claim 2.31 to conclude anything about  $\pi$  we will make use of the following standard lemma:

*Claim 2.32.* For any  $x \in H_\lambda^V$  it holds that  $h(x) = \pi(x) \cap H_\eta^V$ .

PROOF OF CLAIM. For any  $n < \omega$  and  $\langle a_1, \dots, a_n \rangle \in [H_\eta^V]^n$  we have that

$$\begin{aligned} &\langle a_1, \dots, a_n \rangle \in \pi(x) \\ \Leftrightarrow &(\mathcal{M}, \in) \models \langle a_1, \dots, a_n \rangle \in \pi(x) \\ \Leftrightarrow &(\mathcal{M}, \in) \models \langle [\langle a_1 \rangle, \text{pr}], \dots, [\langle a_n \rangle, \text{pr}] \rangle \in [\langle \rangle, c_x] \\ \Leftrightarrow &\langle a_1, \dots, a_n \rangle \in h(\{\langle x_1, \dots, x_n \rangle \mid \mathcal{P}_{\lambda, A} \models \langle x_1, \dots, x_n \rangle \in x\}) \\ \Leftrightarrow &\langle a_1, \dots, a_n \rangle \in h(x), \end{aligned}$$

showing that  $h(x) = \pi(x) \cap H_\eta^V$ . ⊢

Now use Claim 2.31 to fix a  $b \in H_\nu^V$  which is moved by  $h$ . Claim 2.32 then implies that

$$\pi(b) \cap H_\eta^V = h(b) \cap H_\eta^V = h(b) \neq b = b \cap H_\eta^V,$$

showing that  $\pi(b) \neq b$  and hence  $\text{crit } \pi < \nu$ . This finishes the proof. ■

**DEFINITION 2.33.** A cardinal  $\kappa$  is **W-virtually pre-Woodin** if it is virtually pre-Woodin but without requiring that the target model is well-founded. ○

**THEOREM 2.34** (Gitman-N.; GBC). *gWVP holds iff On is W-virtually pre-Woodin.*

**PROOF.** ( $\Leftarrow$ ) is just observing that the virtualisation of the argument in [Wilson, 2019b] that WVP holds if On is Woodin works in the W-virtually pre-Woodin case, so we only give a brief sketch.

Assume On is W-virtually pre-Woodin and let  $\vec{\mathcal{M}}$  be a counterexample to gWVP, so that we in  $V$  have homomorphisms  $\mathcal{M}_\beta \rightarrow \mathcal{M}_\alpha$  for all  $\alpha \leq \beta$ . Work in some generic extension  $V[g]$ , fix a W-virtually  $\vec{\mathcal{M}}$ -prestrong cardinal  $\kappa$  and let  $\theta \gg \kappa$  be such that  $\mathcal{M}_{\kappa+1} \in H_\theta^V$ . Letting  $\pi: (H_\theta^V, \in) \rightarrow (\mathcal{M}, \in^*)$  be the corresponding embedding we get that  $\mathcal{M}_{\kappa+1} = \pi(\vec{\mathcal{M}})_{\kappa+1}$ , so that

$$\pi \upharpoonright \mathcal{M}_\kappa: (\mathcal{M}_\kappa, \in) \rightarrow (\pi(\mathcal{M}_\kappa), \in^*) = (\pi(\vec{\mathcal{M}})_{\pi(\kappa)}, \in^*).$$

But then, by the choice of  $\theta$  and elementarity of  $\pi$ , we get that  $\mathcal{M}$  has a homomorphism

$$h: (\pi(\vec{\mathcal{M}})_{\pi(\kappa)}, \in^*) \rightarrow (\pi(\vec{\mathcal{M}})_{\kappa+1}, \in^*) = (\mathcal{M}_{\kappa+1}, \in),$$

making  $h \circ (\pi \upharpoonright \mathcal{M}_\kappa): (\mathcal{M}_\kappa, \in) \rightarrow (\mathcal{M}_{\kappa+1}, \in)$  a counterexample to gWVP.

( $\Rightarrow$ ): Assume that On is not W-virtually pre-Woodin. This means that there exists a class  $A$  such that there are no W-virtually  $A$ -prestrong cardinals. We can

therefore assign to any cardinal  $\kappa$  the least cardinal  $f(\kappa) > \kappa$  such that  $\kappa$  is not  $W$ -virtually  $(f(\kappa), A)$ -prestrong.

Also define a function  $g: \text{On} \rightarrow \text{Card}$  as taking an ordinal  $\alpha$  to the least singular strong limit cardinal above  $\alpha$  closed under  $f$ . Then we are assuming that there is no non-trivial generic elementary embedding

$$\pi: (H_{g(\alpha)}^V, \in, A \cap H_{g(\alpha)}^V) \rightarrow (\mathcal{M}, \in, B)$$

with  $H_{g(\alpha)}^V \subseteq \mathcal{M}$  and  $B \cap H_{g(\alpha)}^V = A \cap H_{g(\alpha)}^V$ . Assume towards a contradiction that for some  $\alpha, \beta$  there is a non-trivial generic homomorphism  $h: \mathcal{P}_{g(\alpha), A} \rightarrow \mathcal{P}_{g(\beta), A}$ . Lemma 2.27 then gives us a non-trivial generic elementary embedding

$$\pi: (H_{g(\alpha)}^V, \in, A \cap H_{g(\alpha)}^V) \rightarrow (\mathcal{M}, \in, B)$$

for some transitive  $\mathcal{M}$  such that  $H_\nu^V \subseteq \mathcal{M}$  with  $\nu := \min\{g(\alpha), g(\beta)\}$  and  $A \cap H_\nu^V = B \cap H_\nu^V$ , a contradiction! Therefore every generic homomorphism  $h: \mathcal{P}_{g(\alpha), A} \rightarrow \mathcal{P}_{g(\beta), A}$  is trivial. Since there is a unique trivial homomorphism when  $\alpha \geq \beta$  and no trivial homomorphism when  $\alpha < \beta$  since  $g(\alpha)$  is sent to  $g(\beta)$ , the sequence of structures

$$\langle \mathcal{P}_{g(\alpha), A} \mid \alpha \in \text{On} \rangle$$

is a counterexample to  $\text{gWVP}$ , which is what we wanted to show. ■

## 2.3 BERKELEYS

We next move to the higher realms of the virtual large cardinal hierarchy, and study cardinals whose non-virtual versions are inconsistent with  $\text{ZFC}$ .

In the virtual setting the virtually Berkeley cardinals, like all the other virtual large cardinals, are simply downwards absolute to  $L$ . It turns out that virtually Berkeley cardinals are natural objects, as the main theorem of this section, Theorem 2.43, shows that these large cardinals are precisely what separates virtually pre-Woodins from the virtually Woodins, as well as separating virtually Vopěnka cardinals from Mahlo cardinals, improving on a result in [Gitman and Hamkins, 2019].

**DEFINITION 2.35.** Say that a cardinal  $\delta$  is **virtually proto-Berkeley** if for every transitive set  $\mathcal{M}$  such that  $\delta \subseteq \mathcal{M}$  there exists a generic elementary embedding  $\pi: \mathcal{M} \rightarrow \mathcal{M}$  with  $\text{crit } \pi < \delta$ .

If  $\text{crit } \pi$  can be chosen arbitrarily large below  $\delta$  then  $\delta$  is **virtually Berkeley**, and if  $\text{crit } \pi$  can be chosen as an element of any club  $C \subseteq \delta$  we say  $\delta$  is **virtually club Berkeley**.  $\circ$

Note that a quick application of Countable Embedding Absoluteness 1.52 shows that virtually (proto-)Berkeley cardinals are downwards absolute to  $L$ .

We are not interested in the virtually proto-Berkeley cardinals for the same reason we are not interested in the proto-Berkeley cardinals, namely that if  $\delta$  is virtually proto-Berkeley then every  $\kappa > \delta$  is proto-Berkeley as well. The following theorem, which is a straight-forward virtualisation of the corresponding theorem in the non-virtual context, then shows that the least virtually proto-Berkeley cardinal is indeed virtually Berkeley.

**THEOREM 2.36** (Virtualised [Cutolo, 2017] 2.1.14). *The least virtually proto-Berkeley cardinal is virtually Berkeley.*

**PROOF.** Let  $\delta_0$  be the least virtually proto-Berkeley cardinal and assume that  $\eta_0 < \delta_0$  is least such that there exists a transitive set  $\mathcal{M}_0$  with  $\delta_0 \in \mathcal{M}_0$  such that there are no generic elementary embeddings  $\pi: \mathcal{M} \rightarrow \mathcal{M}$  with  $\text{crit } \pi \in (\eta_0, \delta_0)$ .

We will show that  $\eta_0$  is virtually proto-Berkeley, which would contradict minimality of  $\delta_0$ , so let  $\mathcal{M}$  be any transitive set with  $\eta_0 \in \mathcal{M}$ . We can now fix some  $\lambda > \delta_0$  such that  $\mathcal{M}, \mathcal{M}_0 \in V_\lambda$  and define

$$\mathcal{M}' := V_\lambda \cup \{\{\langle x, \eta_0, \mathcal{M}, \mathcal{M}_0 \rangle \mid x \in V_\lambda\}\}.$$

Note that  $\eta_0, \mathcal{M}_0$  and  $\mathcal{M}$  are all definable in  $\mathcal{M}'$ . Use the fact that  $\delta_0$  is virtually proto-Berkeley to get a generic embedding  $\pi: \mathcal{M}' \rightarrow \mathcal{M}'$ , so that definability ensures that  $\pi$  fixes  $\eta_0, \mathcal{M}_0$  and  $\mathcal{M}$ .

By choice of  $\eta_0$  and because  $\mathcal{M}_0$  is fixed by  $\pi$  we get that  $\text{crit } \pi \leq \eta_0$ , and since  $\pi$  fixes  $\eta_0$  we further have that  $\text{crit } \pi < \eta_0$ . This implies that  $\pi \restriction \mathcal{M}: \mathcal{M} \rightarrow \mathcal{M}$

witnesses that  $\eta_0$  is virtually proto-Berkeley,  $\not\leq$ . ■

Virtually (proto-)Berkeley cardinals turn out to be equivalent to their “boldface” versions, the proof of which is a straightforward virtualisation of Lemma 2.1.12 and Corollary 2.1.13 in [Cutolo, 2017].

**PROPOSITION 2.37** (Virtualised [Cutolo, 2017] 2.1.12 and 2.1.13). *If  $\delta$  is virtually proto-Berkeley then for every transitive set  $\mathcal{M}$  such that  $\delta \subseteq \mathcal{M}$  and every subset  $A \subseteq \mathcal{M}$  there exists a generic elementary embedding  $\pi: (\mathcal{M}, \in, A) \rightarrow (\mathcal{M}, \in, A)$  with  $\text{crit } \pi < \delta$ . If  $\delta$  is virtually Berkeley then we can furthermore ensure that  $\text{crit } \pi$  is arbitrarily large below  $\delta$ .*

**PROOF.** Let  $\mathcal{M}$  be transitive with  $\delta \subseteq \mathcal{M}$  and  $A \subseteq \mathcal{M}$ . Let

$$\mathcal{N} := \mathcal{M} \cup \{A, \{\{A, x\} \mid x \in \mathcal{M}\}\} \cup \{\{A, x\} \mid x \in \mathcal{M}\}$$

and note that  $\mathcal{N}$  is transitive. Further, both  $A$  and  $\mathcal{M}$  are definable in  $\mathcal{N}$  without parameters:  $A$  is definable in  $\mathcal{N}$  as the unique set such that there is a set  $B$  ( $= \{\{A, x\} \mid x \in \mathcal{M}\}$ ), all of whose elements are unordered pairs  $\{A, x\}$  and for every  $x \in \mathcal{N}$  such that  $A \not\subseteq x$  and  $x \not\subseteq \{A, B\}$  it holds that  $\{A, x\} \in B$ .  $\mathcal{M}$  is then what remains if we remove all  $x$  such that  $A$  is in the transitive closure of  $x$ . But this means that a generic elementary embedding  $\pi: \mathcal{N} \rightarrow \mathcal{N}$  fixes both  $\mathcal{M}$  and  $A$ , giving us a generic elementary  $\sigma: (\mathcal{M}, \in, A) \rightarrow (\mathcal{M}, \in, A)$  with  $\text{crit } \sigma = \text{crit } \pi$ , yielding the wanted conclusion. ■

The following is a straightforward virtualisation of the usual definition of the Vopěnka filter (see e.g. [Kanamori, 2008]):

**DEFINITION 2.38** (GBC). Define the **virtually Vopěnka filter**  $F$  on  $\text{On}$  as  $X \in F$  iff there is a natural  $\text{On}$ -sequence  $\vec{\mathcal{M}}$  such that  $\text{crit } \pi \in X$  for any  $\alpha < \beta$  and any generic elementary  $\pi: \mathcal{M}_\alpha \rightarrow \mathcal{M}_\beta$ . ◦

Theorem 2.22 shows that  $\emptyset$  is in the virtually Vopěnka filter iff gVP fails, in analogy with the non-virtual case. Normality also holds in the virtual context, as the following proof shows:

**LEMMA 2.39** (Virtualised folklore; GBC). *The virtually Vopěnka filter is a normal filter.*

**PROOF.** Let  $F$  be the virtually Vopěnka filter. We first show that  $F$  is actually a filter. If  $X \in F$  and  $Y \supseteq X$  then  $Y \in F$  simply by definition of  $F$ . If  $X, Y \in F$ , witnessed by natural sequences  $\vec{\mathcal{M}}$  and  $\vec{\mathcal{N}}$ , then  $X \cap Y \in F$  as well, witnessed by the natural sequence  $\vec{\mathcal{P}}$  induced by the indexing function  $f^{\vec{\mathcal{P}}} := \max(f^{\vec{\mathcal{M}}}, f^{\vec{\mathcal{N}}})$  and unary relations  $R_\alpha^{\vec{\mathcal{P}}} := \text{Code}(\langle R_\alpha^{\vec{\mathcal{M}}}, R_\alpha^{\vec{\mathcal{N}}} \rangle)$ . Indeed, if  $\pi: \mathcal{P}_\alpha \rightarrow \mathcal{P}_\beta$  is a generic elementary embedding with critical point  $\mu$  then  $\mu$  is also the critical point of both  $\pi \restriction \mathcal{M}_\alpha: \mathcal{M}_\alpha \rightarrow \mathcal{M}_\beta$  and  $\pi \restriction \mathcal{N}_\alpha: \mathcal{N}_\alpha \rightarrow \mathcal{N}_\beta$ .

For normality, let  $X \in F^+$  be  $F$ -positive, where we recall that this means that  $X \cap C \neq \emptyset$  for every  $C \in F$ , and let  $f: X \rightarrow \text{On}$  be regressive. We want to show that  $f$  is constant on an  $F$ -positive set.

Assume this fails, meaning that there are natural sequences  $\vec{\mathcal{M}}^\gamma$  for  $\gamma$  such that for any generic elementary  $\pi: \mathcal{M}_\alpha^\gamma \rightarrow \mathcal{M}_\beta^\gamma$  satisfies that  $f(\text{crit } \pi) \neq \gamma$ . Define a new natural sequence  $\vec{\mathcal{N}}$  as induced by the indexing function  $g: \text{On} \rightarrow \text{On}$  given as  $g(\alpha) := \sup_{\gamma < \alpha} \text{rk } \mathcal{M}_\alpha^\gamma + \omega$  and unary relations  $R_\alpha^{\vec{\mathcal{N}}}$  given as

$$R_\alpha^{\vec{\mathcal{N}}} := \text{Code}(\langle \langle \mathcal{M}_\alpha^\gamma \mid \gamma < \alpha \rangle, f \restriction \alpha \rangle).$$

Now since  $X$  is  $F$ -positive there exists a generic elementary embedding

$$\pi: \mathcal{N}_\alpha \rightarrow \mathcal{N}_\beta$$

with  $\text{crit } \pi \in X$ . As  $f(\text{crit } \pi) < \text{crit } \pi$  we get that  $\pi(f(\text{crit } \pi)) = f(\text{crit } \pi)$ , so that we have a generic elementary embedding

$$\pi \restriction \mathcal{M}_\alpha^{f(\text{crit } \pi)}: \mathcal{M}_\alpha^{f(\text{crit } \pi)} \rightarrow \mathcal{M}_\beta^{f(\text{crit } \pi)},$$

but this contradicts the definition of  $\vec{\mathcal{M}}^{f(\text{crit } \pi)}$ ! Thus  $F$  is normal. ■

The reason why we are being careful in showing all these analogous properties for the virtual Vopěnka filter is that not all of the properties carry over. Indeed, note

that uniformity of filters is non-trivial as we are working with proper classes<sup>14</sup>, and we will see in Theorem 2.43 that uniformity of this filter is equivalent to there being no virtually Berkeley cardinals – the following lemma is the first implication:

**LEMMA 2.40** (N.; GBC). *Assume  $gVP$  and that there are no virtually Berkeley cardinals. Then the virtually Vopěnka filter  $F$  on  $\mathbf{On}$  contains every class club  $C$ .*

**PROOF.** The crucial extra property we get by assuming that there are not any virtually Berkeleys is that  $F$  becomes uniform, i.e. contains every tail  $(\delta, \mathbf{On}) \subseteq \mathbf{On}$ . Indeed, assume that  $\delta$  is the least cardinal such that  $(\delta, \mathbf{On}) \notin F$ . Let  $M$  be a transitive set with  $\delta \subseteq M$  and  $\gamma < \delta$  a cardinal. As  $(\gamma, \mathbf{On}) \in F$  by minimality of  $\delta$ , we may fix a natural sequence  $\vec{\mathcal{N}}$  witnessing this. Let  $\vec{\mathcal{M}}$  be the natural sequence induced by the indexing function  $f: \mathbf{On} \rightarrow \mathbf{On}$  given by

$$f(\alpha) := \max(\alpha + 1, \delta + 1)$$

and unary relations  $R_\alpha := \{\langle M, \mathcal{N}_\beta \rangle \mid \beta \leq \alpha\}$ . If  $\pi: \mathcal{M}_\alpha \rightarrow \mathcal{M}_\beta$  is a generic elementary embedding with  $\text{crit } \pi \leq \delta$ , which exists as  $(\delta, \mathbf{On}) \notin F$ , then  $\pi(R_\alpha) = R_\beta$  implies that  $\pi \upharpoonright \mathcal{M}: \mathcal{M} \rightarrow \mathcal{M}$  with  $\text{crit } \pi \leq \delta$ . We also get that  $\text{crit } \pi > \gamma$ , as

$$\pi \upharpoonright \mathcal{N}_{\text{crit } \pi}: \mathcal{N}_{\text{crit } \pi} \rightarrow \mathcal{N}_{\pi(\text{crit } \pi)}$$

is an embedding between two structures in  $\vec{\mathcal{N}}$  and hence  $\text{crit } \pi > \gamma$  as  $\vec{\mathcal{N}}$  witnesses that  $(\gamma, \mathbf{On}) \in F$ . This means that  $\delta$  is virtually Berkeley, a contradiction. Thus  $\text{crit } \pi > \delta$ , implying that  $(\delta, \mathbf{On}) \in F$ .

Note that the class  $C_0 \subseteq \mathbf{On}$  of limit ordinals is in  $F$ , since it is the diagonal intersection of the tails  $(\alpha + 1, \mathbf{On})$ . Now let  $C \subseteq \mathbf{On}$  be a class club, and let

$$C := \{a_\alpha \mid \alpha < \mathbf{On}\}$$

be its increasing enumeration. Then  $C \supseteq C_0 \cap \Delta_{\alpha < \mathbf{On}}(a_\alpha, \mathbf{On})$ , implying that  $C \in F$ . ■

---

<sup>14</sup>This boils down to the fact that the class club filter is not provably normal in GBC, see [Gitman et al., 2019]

**THEOREM 2.41** (N.; GBC). *If there are no virtually Berkeley cardinals then  $\text{On}$  is virtually pre-Woodin iff  $\text{On}$  is virtually Woodin.*

**PROOF.** Assume  $\text{On}$  is virtually pre-Woodin, so  $\text{gVP}$  holds by Theorem 2.22 and we can let  $F$  be the virtually Vopěnka filter. The assumption that there are not any virtually Berkeley cardinals implies that for any class  $A$  we not only get a virtually  $A$ -prestrong cardinal, but we get stationarily many such. Indeed, assume this fails – we will follow the proof of Theorem 2.22.

Failure means that there is some class  $A$  and some class club  $C$  such that there are no virtually  $A$ -prestrong cardinals in  $C$ . Since there are no virtually Berkeley cardinals, Lemma 2.40 implies that  $C \in F$ , so there exists some natural sequence  $\vec{\mathcal{N}}$  such that whenever  $\pi: \mathcal{N}_\alpha \rightarrow \mathcal{N}_\beta$  is an elementary embedding between two distinct structures of  $\vec{\mathcal{N}}$  it holds that  $\text{crit } \pi \in C$ . Define  $f: \text{On} \rightarrow \text{On}$  as sending  $\alpha$  to the least cardinal  $\eta > \alpha$  such that  $\alpha$  is not virtually  $(\eta, A)$ -prestrong if  $\alpha \in C$ , and set  $f(\alpha) := \alpha$  if  $\alpha \notin C$ . Also define  $g: \text{On} \rightarrow \text{On}$  as  $g(\alpha)$  being the least strong limit cardinal in  $C$  above  $\alpha$  which is a closure point for  $f$ .

Now let  $\vec{\mathcal{M}}$  be the natural sequence induced by  $g$  and

$$R_\alpha := \text{Code}(\langle A \cap H_{g(\alpha)}^V, \mathcal{N}_\alpha \rangle)$$

and apply  $\text{gVP}$  to get  $\alpha < \beta$  and a generic elementary embedding  $\pi: \mathcal{M}_\alpha \rightarrow \mathcal{M}_\beta$ , which restricts to

$$\pi \restriction (H_{g(\alpha)}^V, \in, A \cap H_{g(\alpha)}^V): (H_{g(\alpha)}^V, \in, A \cap H_{g(\alpha)}^V) \rightarrow (H_{g(\beta)}^V, \in, A \cap H_{g(\beta)}^V),$$

making  $\text{crit } \pi$  virtually  $(g(\alpha), A)$ -prestrong and thus  $\text{crit } \pi \notin C$ . But as we also get the embedding  $\pi \restriction \mathcal{N}_\alpha: \mathcal{N}_\alpha \rightarrow \mathcal{N}_\beta$ , we have that  $\text{crit } \pi \in C$  by definition of  $\vec{\mathcal{N}}$ ,  $\nmid$ .

Now fix any class  $A$  and some large  $n < \omega$  and define the class

$$C := \{\kappa \in \text{Card} \mid (H_\kappa^V, \in, A \cap H_\kappa^V) \prec_{\Sigma_n} (V, \in, A)\}.$$

This is a club and we can therefore find a virtually  $A$ -prestrong cardinal  $\kappa \in C$ . Assume that  $\kappa$  is not virtually  $A$ -strong and let  $\theta$  be least such that it is not virtually

$(\theta, A)$ -strong. Fix a generic elementary embedding

$$\pi: (H_\theta^V, \in, A \cap H_\theta^V) \rightarrow (M, \in, B)$$

with  $\text{crit } \pi = \kappa$ ,  $H_\theta^V \subseteq M$ ,  $M \subseteq V$ ,  $A \cap H_\theta^V = B \cap H_\theta^V$  and  $\pi(\kappa) < \theta$ .

Now  $\pi(\kappa)$  is inaccessible, and  $(H_{\pi(\kappa)}^V, \in, A \cap H_{\pi(\kappa)}^V) = (H_{\pi(\kappa)}^M, \in, B \cap H_{\pi(\kappa)}^M)$  believes that  $\kappa$  is virtually  $(A \cap H_{\pi(\kappa)}^V)$ -strong as in the proof of Theorem 2.10, meaning that  $(H_\kappa^V, \in, A \cap H_\kappa^V)$  believes that there is a proper class of virtually  $(A \cap H_\kappa^V)$ -strong cardinals. But  $\kappa \in C$ , which means that

$$(V, \in, A) \models \ulcorner \text{There exists a proper class of virtually } A\text{-strong cardinals} \urcorner,$$

implying that On is virtually Woodin. ■

Next, the following result is an improvement of a theorem in [Gitman and Hamkins, 2019], reducing the assumption of the existence of  $0^\sharp$  to the existence of a virtually Berkeley cardinal, which we will later see is optimal:

**THEOREM 2.42** (N.; GBC). *If there exists a virtually Berkeley cardinal  $\delta$  then gVP holds and On is not Mahlo.*

**PROOF.** If On was Mahlo then there would in particular exist an inaccessible cardinal  $\kappa > \delta$ , but then  $H_\kappa^V \models \ulcorner \text{there exists a virtually Berkeley cardinal} \urcorner$ , contradicting the incompleteness theorem, as we would have shown that

$$\text{GBC} + \Phi \vdash \text{Con}(\text{GBC} + \Phi),$$

witnessed by the model  $(H_\kappa^V, \mathcal{P}^V(H_\kappa^V))$ , with  $\Phi$  being “There exists a virtually Berkeley cardinal”.

To show gVP we show that On is virtually pre-Woodin, which is equivalent by Theorem 2.22. Fix therefore a class  $A$  – we have to show that there exists a virtually  $A$ -prestrong cardinal. For every cardinal  $\theta \geq \delta$  there exists a generic elementary embedding

$$\pi_\theta: (H_\theta^V, \in, A \cap H_\theta^V) \rightarrow (H_\theta^V, \in, A \cap H_\theta^V)$$

with  $\text{crit } \pi < \delta$ . By the pigeonhole principle we thus get some  $\kappa < \delta$  which is the critical point of proper class many  $\pi_\theta$ , showing that  $\kappa$  is virtually  $A$ -prestrong, making  $\text{On}$  virtually pre-Woodin. ■

**THEOREM 2.43** (N.; GBC). *The following are equivalent:*

- (i) *if gVP holds then On is Mahlo;*
- (ii) *On is virtually pre-Woodin iff On is virtually Woodin;*
- (iii) *There are no virtually Berkeley cardinals.*

PROOF.  $(iii) \Rightarrow (ii)$  is Theorem 2.41, and the contraposited version of  $(i) \Rightarrow (iii)$  is Theorem 2.42. For  $(ii) \Rightarrow (i)$  note that gVP implies that  $\text{On}$  is virtually pre-Woodin by Theorem 2.22, which by  $(ii)$  means that it is virtually Woodin and the usual proof shows that virtually Woodins are Mahlo<sup>15</sup>, showing  $(i)$ . ■

This also immediately implies the following equiconsistency, as virtually Berkeley cardinals have strictly larger consistency strength than virtually Woodin cardinals:

**COROLLARY 2.44** (N.). *The existence of an inaccessible virtually pre-Woodin cardinal is equiconsistent with the existence of an inaccessible virtually Woodin cardinal.* ■

## 2.4 BEHAVIOUR IN CORE MODELS

Most of the cardinals turn out to be downwards absolute to most inner models, including  $L$ .

**PROPOSITION 2.45.** *For any regular uncountable cardinal  $\theta$ , faintly  $\theta$ -measurable cardinals are downwards absolute to any transitive class  $\mathcal{U} \subseteq V$  satisfying  $ZF^- + DC$ .*

PROOF. Let  $\kappa$  be faintly  $\theta$ -measurable, witnessed by a forcing poset  $\mathbb{P}$  and a  $V$ -generic  $g \subseteq \mathbb{P}$  such that, in  $V[g]$ , there is a transitive  $\mathcal{M}$  and an elementary embedding  $\pi: H_\theta^V \rightarrow \mathcal{M}$  with  $\text{crit } \pi = \kappa$ . Fix a transitive class  $\mathcal{U} \subseteq V$  which

<sup>15</sup>See e.g. Exercise 26.10 in [Kanamori, 2008].

satisfies  $\text{ZF}^- + \text{DC}$ . Restricting the embedding to  $\pi \upharpoonright H_\theta^{\mathcal{U}}: H_\theta^{\mathcal{U}} \rightarrow \mathcal{N}$  we can now apply the Countable Absoluteness Lemma 1.52 to  $\pi \upharpoonright H_\theta^{\mathcal{U}}$  to get that there exists an embedding  $\pi^*: H_\theta^{\mathcal{U}} \rightarrow \mathcal{N}^*$  in a generic extension of  $U$ , making  $\kappa$  faintly  $\theta$ -measurable in  $\mathcal{U}$ . ■

**THEOREM 2.46 (N.).** *Let  $\theta$  be a regular uncountable cardinal.*

- (i)  $L \models \ulcorner \text{faintly } \theta\text{-measurables are equivalent to virtually } \theta\text{-prestrongs} \urcorner$ .
- (ii) Assume that  $L[\mu]$  exists. It then holds that
  - $L[\mu] \models \ulcorner \text{faintly } \theta\text{-measurables are equivalent to virtually } \theta\text{-measurables} \urcorner$ .
- (iii) Assume there is no inner model with a Woodin. It then holds that
  - $K \models \ulcorner \text{faintly } \theta\text{-measurables are equivalent to virtually } \theta\text{-measurables} \urcorner$ .

PROOF. For (i) simply note that if  $\pi: L_\theta \rightarrow \mathcal{N}$  is a generic elementary embedding with  $\mathcal{N}$  transitive, then by condensation we have that  $\mathcal{N} = L_\gamma$  for some  $\gamma \geq \theta$ , so that  $\pi$  also witnesses the virtual  $\theta$ -prestrongness of  $\text{crit } \pi$ .

(ii): Assume that  $V = L[\mu]$  for notational simplicity and let  $\kappa$  be faintly  $\theta$ -measurable, witnessed by a generic elementary embedding  $\pi: L_\theta[\mu] \rightarrow \mathcal{N}$  existing in some generic extension  $V[g]$ . By condensation we get that  $\mathcal{N} = L_\gamma[\bar{\mu}]$  for some  $\gamma \geq \theta$  and  $\bar{\mu} \in V[g]$ , but we are not guaranteed that  $\bar{\mu} \in V$  here. Let  $\lambda$  be the unique measurable cardinal of  $V = L[\mu]$ .

Note that  $\bar{\mu}$  is a measure on  $\pi(\lambda) \geq \lambda$ . If  $\pi(\lambda) = \lambda$  then  $L[\mu] = L[\bar{\mu}]$  by [Kanamori, 2008, Kunen's Theorem 20.10] and we trivially get that  $\mathcal{N} \subseteq V$ . Assume thus that  $\pi(\lambda) > \lambda$ , which implies that  $L[\bar{\mu}]$  is an internal iterate of  $L[\mu]$  by [Kanamori, 2008, Kunen's Theorem 20.12]. In particular it then holds that  $L[\bar{\mu}] \subseteq L[\mu]$ , so again we get that  $\mathcal{N} \subseteq V$ .

(iii): Assume that  $V = K = L[\mathcal{E}]$  and fix a faintly  $\theta$ -measurable cardinal  $\kappa$ , witnessed by a generic embedding  $\pi: L_\theta[\mathcal{E}] \rightarrow \mathcal{N} = L_\gamma[\bar{\mathcal{E}}]$  in some generic extension  $V[g]$ . Now coiterate<sup>16</sup>  $L[\mathcal{E}]$  with  $L[\bar{\mathcal{E}}]$ , and denote the last models by  $\mathcal{P}$  and  $\mathcal{Q}$ . Since  $K = K^{V[g]}$  and as  $K$  is universal we get that  $\mathcal{Q} \leq \mathcal{P}$ . Then the  $L[\bar{\mathcal{E}}]$ -to- $\mathcal{Q}$  branch did not drop, giving us an iteration embedding  $i: L[\bar{\mathcal{E}}] \rightarrow \mathcal{Q}$ .

Note that  $\text{crit } i \geq \kappa$  as  $\bar{\mathcal{E}}$  is simply the pointwise image of  $\mathcal{E}$  under  $\pi$ , so nothing below  $\kappa$  is touched and is therefore not used in the comparison either. This

<sup>16</sup>See Section 1.4 for more information about the core model  $K$  and coiterations.

means that  $\text{crit}(i \circ \pi) = \kappa$ , so that  $(i \circ \pi): L_\theta[\mathcal{E}] \rightarrow \mathcal{Q}$  witnesses that  $\kappa$  is virtually  $\theta$ -measurable, since  $\mathcal{Q} \trianglelefteq \mathcal{P}$  implies that  $\mathcal{Q} \subseteq K$ . ■

Note that the proofs of (ii) and (iii) above do not show that  $\kappa$  is virtually  $\theta$ -prestrong, as it might still be the case that  $\bar{\mu} \neq \mu$  or  $\bar{\mathcal{E}} \neq \mathcal{E}$ , so we cannot conclude that  $L_\theta[\mu] \subseteq L_\theta[\bar{\mu}]$  or  $L_\theta[\mathcal{E}] \subseteq L_\theta[\bar{\mathcal{E}}]$ . It might still hold however; see Question 5.2.

## 2.5 SEPARATION RESULTS

Having proven many positive results about the relations between the virtual large cardinals in the previous sections, this section is dedicated to the negatives. More precisely, we will aim to *separate* many of the defined notions (potentially under suitable large cardinal assumptions). See Figure 2.2 for an overview of the relations between the various level-wise faint- and virtual large cardinals.

Our first separation result is that the virtuals form a level-by-level hierarchy.

**THEOREM 2.47 (N).** *Let  $\alpha < \kappa$  and assume that  $\kappa$  is faintly  $\kappa^{+\alpha+2}$ -measurable. Then*

$$L_\kappa \models \ulcorner \text{There is a proper class of } \lambda \text{ which are virtually } \lambda^{+\alpha+1}\text{-strong} \urcorner.$$

**PROOF.** Write  $\theta := \kappa^{+\alpha+1}$ . Then by Theorem 2.10 we get that either  $\kappa$  is faintly  $\theta^+$ -strong in  $L$  or otherwise, in particular,  $L_\kappa$  thinks that there is a proper class of remarkables. In the second case we also get that  $L_\kappa$  thinks that there is a proper class of  $\lambda$  such that  $\lambda$  is virtually  $\lambda^{+\alpha+1}$ -strong and we would be done, so assume the first case. Then  $L_\kappa \prec_2 L_{\theta^+}$ , so define for each  $\xi < \kappa$  the sentence  $\psi_\xi$  as

$$\psi_\xi := \exists \lambda > \xi: \ulcorner \lambda \text{ is virtually } \lambda^{+\alpha+1}\text{-strong} \urcorner.$$

Then  $\psi_\xi$  is  $\Sigma_2(\{\alpha, \xi\})$  since being virtually  $\beta$ -strong is a  $\Delta_2(\{\beta\})$ -statement. As  $L_{\theta^+} \models \psi_\xi$  for all  $\xi < \kappa$  we also get that  $L_\kappa \models \psi_\xi$  for all  $\xi < \kappa$ , which is what we wanted to show. ■

As we are only assuming  $\kappa$  to be *faintly* measurable in the above, this also shows that the faintly  $\kappa^{+\alpha+1}$ -measurable cardinals  $\kappa$  form a strict hierarchy whenever  $\alpha < \kappa$ .

A separation result in a similar vein is the following, showing that it is consistent to have an inaccessible faintly measurable cardinal which is not weakly compact:

**PROPOSITION 2.48 (N).** *Assuming  $\kappa$  is measurable, there is a generic extension of  $V$  in which  $\kappa$  is inaccessible and faintly measurable, but not weakly compact.*

**PROOF.** Let  $\mathbb{P}$  be the forcing notion that adds a  $\kappa$ -Suslin tree  $\mathcal{T}$ . By [Kunen, 1978] it then holds that  $\mathbb{P} * \mathcal{T} \cong \text{Add}(\kappa^+, 1)$ , a  $<\kappa^+$ -closed forcing, which preserves the measurability of  $\kappa$ . Further, the  $\mathbb{P}$  forcing is shown to preserve the inaccessibility of  $\kappa$ , making  $\kappa$  inaccessible and faintly measurable in  $V[g]$ . Lastly, it cannot be weakly compact in  $V[g]$  because  $\mathcal{T}$  is a  $\kappa$ -tree without a branch, by definition. ■

Next, we show that the virtuals are in fact different from the faints. This is trivial in general as successor cardinals can be faintly measurable and are never virtually measurable, but the separation still holds true if we rule out this successor case.

For a slightly more fine-grained distinction let us define an intermediate large cardinal between the faintly and virtual.

**DEFINITION 2.49.** Let  $\kappa < \theta$  be infinite regular cardinals. Say that  $\kappa$  is **faintly  $\theta$ -power- $\Phi$**  for  $\Phi \in \{\text{measurable, prestrong, strong}\}$  if it is faintly  $\theta$ - $\Phi$ , witnessed by an embedding  $\pi: H_\theta^V \rightarrow \mathcal{N}$ , and  $\mathcal{P}^V(\kappa) = \mathcal{P}^\mathcal{N}(\kappa)$ . ◻

Note that the proof of Lemma 2.2 shows that faintly power-measurables are also 1-iterable and so in particular weakly compact. Our separation result is then the following:

**THEOREM 2.50 (Gitman-N).** *For  $\Phi \in \{\text{measurable, prestrong, strong}\}$ , if  $\kappa$  is virtually  $\Phi$ , then there exist forcing extensions  $V[G]$  and  $V[G^*]$  such that*

- (i) *in  $V[G]$ ,  $\kappa$  is inaccessible and faintly  $\Phi$ , but not faintly power- $\Phi$ , and*
- (ii) *in  $V[G^*]$ ,  $\kappa$  is faintly power- $\Phi$ , but not virtually  $\kappa^{++}$ -prestrong.*

PROOF. We start with (i). Let us assume that  $\kappa$  is virtually measurable. This implies, in particular, that for every regular  $\theta > \kappa$ , we have generic embeddings  $\pi : H_\theta \rightarrow \mathcal{M}$  with  $\text{crit } \pi = \kappa$  such that  $\mathcal{M} \in V$ . Thus, by Proposition 1.53, we can assume that the generic embedding  $\pi$  exists in a  $\text{Col}(\omega, H_\theta)$ -extension.

Let  $\mathbb{P}_\kappa$  be the Easton support iteration that adds a Cohen subset to every regular  $\alpha < \kappa$ , and let  $G \subseteq \mathbb{P}_\kappa$  be  $V$ -generic. Standard computations show that  $\mathbb{P}_\kappa$  preserves all inaccessible cardinals.

Fix a regular  $\theta \gg \kappa$  and let  $h \subseteq \text{Col}(\omega, H_\theta)$  be  $V[G]$ -generic. In  $V[h]$ , we must have an elementary embedding  $\pi : H_\theta \rightarrow \mathcal{M}$  with  $\text{crit } \pi = \kappa$  and  $\mathcal{M} \in V$ , and we can assume without loss that  $\mathcal{M}$  is countable. Obviously,  $\pi \in V[G][h]$ . Working in  $V[G][h]$ , we will now lift  $\pi$  to an elementary embedding on  $H_\theta[G]$ . To ensure that such a lift exists, it suffices to find in  $V[G][h]$  an  $\mathcal{M}$ -generic filter for  $\pi(\mathbb{P}_\kappa)$  containing  $\pi''G$ <sup>17</sup>. Observe first that  $\pi''G = G$  since the critical point of  $\pi$  is  $\kappa$  and we can assume that  $\mathbb{P}_\kappa \subseteq V_\kappa$ . Next, observe that  $\pi(\mathbb{P}_\kappa) \cong \mathbb{P}_\kappa * \mathbb{P}_{\text{tail}}$ , where  $\mathbb{P}_{\text{tail}}$  is the forcing beyond  $\kappa$ . Since  $\mathcal{M}[G]$  is countable, we can build an  $\mathcal{M}[G]$ -generic filter  $G_{\text{tail}}$  for  $\mathbb{P}_{\text{tail}}$  in  $V[G][h]$ . Thus,  $G * G_{\text{tail}}$  is  $\mathcal{M}$ -generic for  $\pi(\mathbb{P}_\kappa)$ , and so we can lift  $\pi$  to  $\pi : H_\theta[G] \rightarrow \mathcal{M}[G][G_{\text{tail}}]$ . Since  $\theta$  was chosen arbitrarily, we have just shown that  $\kappa$  is faintly measurable in  $V[G]$ .

Now suppose that  $\kappa$  is faintly power-measurable in  $V[G]$ . Fix regular  $\theta < \bar{\theta}$  and a generic elementary embedding  $\sigma : H_{\bar{\theta}}[G] \rightarrow \mathcal{N}$  with  $\text{crit } \sigma = \kappa$  and  $\mathcal{P}(\kappa)^{V[G]} = \mathcal{P}(\kappa)^\mathcal{N}$ . By elementarity,  $H_{\sigma(\theta)}^\mathcal{N} = \sigma(H_\theta)[\sigma(G)]$  is a forcing extension of  $K = \sigma(H_\theta)$  by  $\sigma(G) = G * \bar{G}_{\text{tail}} \subseteq \sigma(\mathbb{P}_\kappa) \cong \mathbb{P}_\kappa * \bar{\mathbb{P}}_{\text{tail}}$ . Thus, we have the restrictions  $\sigma : H_\theta \rightarrow K$  and  $\sigma : H_\theta[G] \rightarrow K[G][\bar{G}_{\text{tail}}]$ . Let us argue that  $\mathcal{P}^{V[G]}(\kappa) \subseteq \mathcal{P}^{K[G]}(\kappa)$ , and hence we have equality. Suppose  $A \subseteq \kappa$  in  $V[G]$  and let  $\dot{A}$  be a nice  $\mathbb{P}_\kappa$ -name for  $A$ , which can be coded by a subset of  $\kappa$ . Since  $\text{crit } \sigma = \kappa$ , we have that  $\dot{A} \in K$ , and hence  $A = \dot{A}_G \in K[G]$ . But now it follows that the  $K[G]$ -generic for  $\text{Add}(\kappa, 1)$ , the forcing at stage  $\kappa$  in  $\sigma(\mathbb{P}_\kappa)$ , cannot be in  $V[G]$ . Thus, we have reached a contradiction, showing that  $\kappa$  cannot be faintly power-measurable in  $V[G]$ .

If  $\Phi = \text{measurable}$ , then we are done at this point. For  $\Phi = \text{prestrong}$  we simply note that  $G \in \mathcal{M}[G * G_{\text{tail}}]$  so that  $H_\theta^{V[G]} \subseteq \mathcal{N}[G * G_{\text{tail}}]$  as well, and since we lifted  $\pi$ , we still have  $\pi(\kappa) > \theta$  in the  $\Phi = \text{strong}$  case.

<sup>17</sup>This standard lemma is referred to in the literature as the **lifting criterion**.

For (ii), we change  $\mathbb{P}_\kappa$  to only add Cohen subsets to *successor* cardinals  $\lambda < \kappa$  and call the resulting forcing  $\mathbb{P}_\kappa^*$ . Let  $G^* \subseteq \mathbb{P}_\kappa^*$  be  $V$ -generic. We verify that  $\kappa$  is faintly- $\Phi$  as above by lifting an embedding  $\pi : H_\theta \rightarrow \mathcal{M}$ , with  $\mathcal{M} \subseteq V$ , to

$$\pi : H_\theta[G^*] \rightarrow \mathcal{M}[G^*][G_{\text{tail}}]$$

in a collapse extension  $V[G^*][h]$ . The lifted embedding is  $\kappa$ -powerset preserving because a subset of  $\kappa$  from  $\mathcal{M}[G^*][G_{\text{tail}}]$  has to already be in  $\mathcal{M}[G^*]$  as  $\mathbb{P}_{\text{tail}}$  is  $\leq \kappa$ -closed, and  $\mathcal{M}[G^*] \subseteq V[G^*]$ . So it remains to show that  $\kappa$  is not virtually  $\kappa^{++}$ -prestrong. Suppose it is and fix a generic embedding  $\sigma : H_{\kappa^{++}}[G^*] \rightarrow K[G^*][G_{\text{tail}}]$  with  $\text{crit } \sigma = \kappa$  and  $H_{\kappa^{++}}[G^*] \subseteq K[G^*][G_{\text{tail}}]$ . It follows that the generic subset of  $\kappa^+$  added at stage  $\kappa^+$  by the tail forcing must be  $V[G^*]$ -generic, which is contradictory.  $\blacksquare$

Starting from a much stronger hypothesis, it can be shown that a power-measurable cardinal need not even be virtually  $\kappa^+$ -measurable.

To see this, we first observe that virtually  $\theta$ -measurable cardinals  $\kappa$  are  $\Pi_1^2$ -indescribable for all  $\theta > \kappa$ . The proof is identical to the standard Hanf-Scott proof that measurable cardinals are  $\Pi_1^2$ -indescribable; see e.g. Hanf-Scott's Proposition 6.5 in [Kanamori, 2008]. It should be noted that we crucially need the “virtual” property for the proof to go through.

Using this indescribability fact, the proof of the following theorem is precisely the same as Hamkins' Proposition 8.2 in [Holy and Schlicht, 2018]:

**THEOREM 2.51** (Virtualised Hamkins). *Assuming  $\kappa$  is a  $\kappa^{++}$ -tall cardinal,<sup>18</sup> there is a forcing extension in which  $\kappa$  is not virtually  $\kappa^+$ -measurable, but becomes measurable in a further  $\text{Add}(\kappa^+, 1)$ -generic extension.*

This then immediately gives the separation result.

**COROLLARY 2.52.** *Assuming  $\kappa$  is a  $\kappa^{++}$ -tall cardinal, it is consistent that  $\kappa$  is faintly power-measurable, but not virtually  $\kappa^+$ -measurable.*

---

<sup>18</sup>Recall that  $\kappa$  is  $\kappa^{++}$ -**tall** if there is an elementary embedding  $j : V \rightarrow M$  with  $\text{crit } j = \kappa$ ,  ${}^\kappa M \subseteq M$  and  $j(\kappa) > \kappa^{++}$ .

PROOF. By the above Theorem 2.51 we may assume that  $\kappa$  is not virtually  $\kappa^+$ -measurable but that it is measurable in  $V^{\mathbb{P}}$  for  $\mathbb{P} := \text{Add}(\kappa^+, 1)$ , so that  $\kappa$  is faintly power-measurable. ■

In contrast to the above separation result, note that we showed in Corollary 2.18 and Theorem 2.22 that the faint-virtual distinction vanishes when we are dealing with virtual pre-Woodin or Woodin cardinals.

Our next separation result is concerning the virtually prestrong and virtually strong cardinals.

**COROLLARY 2.53 (N.).** *There exists a virtually rank-into-rank cardinal iff there is an uncountable cardinal  $\theta$  and a virtually  $\theta$ -prestrong cardinal which is not virtually  $\theta$ -strong.*

PROOF. ( $\Leftarrow$ ) is directly from the above Proposition 2.11 and Theorem 2.10.

( $\Rightarrow$ ): Here we have to show that if there exists a virtually rank-into-rank cardinal then there exists a  $\theta > \kappa$  and a virtually  $\theta$ -prestrong cardinal which is not virtually  $\theta$ -strong. Let  $(\kappa, \theta)$  be the lexicographically least pair such that  $\kappa$  is virtually  $\theta$ -rank-into-rank, which trivially makes  $\kappa$  virtually  $\theta$ -prestrong. If  $\kappa$  was also virtually  $\theta$ -strong then it would be  $\Sigma_2$ -reflecting<sup>19</sup>, so that the statement that there exists a virtually rank-into-rank cardinal would reflect down to  $H_\kappa^V$ , contradicting the minimality of  $\kappa$ . ■

Figure 2.2 summarises the separation results along with the results from Section 2.4. Note that it *might* be the case that virtually  $\theta$ -measurables are always virtually  $\theta$ -prestrong (and hence also equivalent in  $L[\mu]$  and  $K$  below a Woodin cardinal); see Question 5.2.

## 2.6 INDESTRUCTIBILITY

It is well-known that supercompact cardinals  $\kappa$  can be made indestructible by all  $<\kappa$ -directed closed forcings by a suitable *Laver preparatory forcing*, which is the main theorem in the seminal paper [Laver, 1978]. A natural question, then, is whether similar results hold for the faintly and virtual versions. We noted in

<sup>19</sup>See Exercise 20.18 in [Jech, 2006], and Section 1.3 for a definition of  $\Sigma_n$ -reflecting cardinals.

Figure 2.2: Direct implications between virtuals, where the red lines with crosses indicate that ZFC does not prove the reverse implication.

Proposition 2.2 that the virtuals are weakly compact, so the following theorem from [Jensen et al., 2009] shows that the consistency strength of indestructible virtual supercompacts is very large, potentially even in the realm of supercompacts:

**THEOREM 2.54** (Schindler). *The consistency strength of a weakly compact cardinal  $\kappa$  which is indestructible by  $<\kappa$ -directed closed forcing is larger than the consistency strength of a proper class of strong cardinals and a proper class of Woodin cardinals.*

This gets close to resolving the question about the indestructible virtuals, so what about the faintly supercompact cardinals? To make things a bit easier for ourselves, let us make the notion a bit stronger.

**DEFINITION 2.55.** Fix uncountable cardinals  $\kappa < \theta$ . Then  $\kappa$  is **generically setwise  $\theta$ -supercompact** if there exists a generic extension  $V[g]$ , a transitive  $\mathcal{N} \in V[g]$  and a generic elementary embedding  $\pi: H_\theta^V \rightarrow \mathcal{N}$ ,  $\pi \in V[g]$ , with  $\text{crit } \pi = \kappa$ ,

$\pi(\kappa) > \theta$  and  $V[g] \models {}^{<\theta}\mathcal{N} \subseteq \mathcal{N}$ . If it holds for all  $\theta > \kappa$  then we say that  $\kappa$  is **generically setwise supercompact**.  $\circ$

Note that the only difference between a generically setwise  $\theta$ -supercompact cardinal and a virtually  $\theta$ -supercompact cardinal is that the former is closed under sequences *in the generic extension*, where the latter is only closed under sequences in  $V$ ; i.e., that  $V \cap {}^{<\theta}\mathcal{N} \subseteq \mathcal{N}$ .

Ostensibly this seems to be an incredibly strong notion, as the target model now inherits a lot of structure from the generic extension. A first stab at an upper consistency bound could be to note that if there exists a proper class of Woodin cardinals then  $\omega_1$  is generically setwise supercompact. This can be shown using the countable stationary tower, see 2.7.7 and 2.7.8 in [Larson, 2004].

But, surprisingly, the following result from Usuba shows that they can exist in  $L$ :

**THEOREM 2.56** ([Usuba, TBA]). *If  $\kappa$  is virtually extendible then  $\text{Col}(\omega, <\kappa)$  forces that  $\omega_1$  is generically setwise supercompact.*  $\blacksquare$

It turns out that this slightly stronger notion *does* have indestructibility properties. We warm up by firstly showing that they are indestructible by small forcing.

**PROPOSITION 2.57** (N.-Schlicht). *Generic setwise supercompactness of  $\kappa$  is indestructible for forcing notions of size  $< \kappa$ .*

**PROOF.** Fix a forcing  $\mathbb{P}$  of size  $< \kappa$  and assume without loss of generality that  $\mathbb{P} \in H_\kappa^V$ , and fix also a cardinal  $\theta > \kappa$ . Using the setwise supercompactness of  $\kappa$  we may fix a forcing  $\mathbb{Q}$  and a  $V$ -generic  $h \subseteq \mathbb{Q}$  such that in  $V[h]$  we have an elementary  $\pi: M := H_\theta^V \rightarrow \mathcal{N}$  in  $V[h]$  with  $\mathcal{N}$   $<\theta$ -closed.

Let  $g \subseteq \mathbb{P}$  be  $V[h]$ -generic and work in  $V[g \times h]$ . By the Lifting Criterion 1.51 we get a lift  $\tilde{\pi}: M[g] \rightarrow \mathcal{N}[g]$  of  $\pi$ . If  $\kappa$  is a limit cardinal, then we may choose a cardinal  $\lambda < \kappa$  such that  $\mathbb{P} \in H_\lambda^V$ . Since  $\mathbb{P}$  has the  $\lambda^+$ -cc in  $V$  we get that  $\pi(\mathbb{P}) = \mathbb{P}$  has the  $\lambda^+$ -cc in  $\mathcal{N}$  and hence in  $V[h]$  as well, making  $\mathcal{N}[g]$   $<\theta$ -closed by Lemma 1.54 and we are done.

If  $\kappa = \nu^+$ , then there are no cardinals between  $\nu$  and  $\pi(\kappa)$  in  $\mathcal{N}$  and hence  $|\theta| \leq \nu$ . Thus it suffices to show that  $\mathcal{N}[g]$  is  $\nu$ -closed. Since  $\pi(\mathbb{P}) = \mathbb{P}$  has size  $\leq \nu$  in  $V$ , it has the  $\nu^{+V[h]}$ -cc in  $V[h]$ . Therefore  $\mathcal{N}[g]$  is again  $<\theta$ -closed by Lemma 1.54.  $\blacksquare$

Next, we show that these generic setwise supercompact cardinals  $\kappa$  are in fact indestructible for  $<\kappa$ -directed closed forcings, without having to do any preparation forcing at all.

**THEOREM 2.58** (N-Schlicht). *Generic setwise supercompactness of  $\kappa$  is indestructible for  $<\kappa$ -directed closed forcings.*

**PROOF.** Suppose that  $\kappa$  is generically setwise supercompact,  $\mathbb{P}$  is a  $<\kappa$ -directed closed forcing and  $g$  is  $\mathbb{P}$ -generic over  $V$ . We will show that  $\kappa$  is generically setwise supercompact in  $V[g]$ .

In  $V$  fix a regular  $\theta > \kappa$  such that  $\mathbb{P} \in H_\theta^V$ , and let  $\mathbb{Q}$  be the forcing given by the definition of setwise supercompactness. Let  $h$  be  $\mathbb{Q}$ -generic over  $V[g]$ . Let  $\pi: H_\theta^V \rightarrow \mathcal{N}$  be as in the definition of generically setwise supercompactness, so that  $\pi \in V[h] \subseteq V[g \times h]$ . Work in  $V[g \times h]$ .

We may assume that  $\theta = \theta^{<\theta}$  holds, as otherwise we just replace  $\mathbb{Q}$  with  $\mathbb{Q} * \text{Col}(\theta, \theta^{<\theta})$  – we retain the  $<\theta$ -closure of  $\mathcal{N}$  because  $\text{Col}(\theta, \theta^{<\theta})$  is  $<\theta$ -closed. We can further assume that  $|\mathcal{N}| = \theta^{<\theta} = \theta$ , as otherwise we can take a hull of  $\mathcal{N}$  containing  $\text{ran}(\pi)$  and recursively close under  $<\theta$ -sequences, ending up with a  $<\theta$ -closed elementary substructure  $\mathcal{H} \prec \mathcal{N}$  containing  $\text{ran}(\pi)$  – now replace  $\mathcal{N}$  by the transitive collapse of  $\mathcal{H}$ .

*Claim 2.59.* There is a  $\pi(\mathbb{P})$ -generic filter  $\tilde{g}$  over  $\mathcal{N}$  that extends  $\pi[g]$ .

**PROOF OF CLAIM.** Since  $\mathcal{N}$  is (in particular)  $|\mathbb{P}|$ -closed in  $V[h]$  and  $\mathbb{P}$  is trivially  $|\mathbb{P}|^+$ -cc, Lemma 1.54 implies that  $\mathcal{N}$  is still  $|\mathbb{P}|$ -closed in  $V[g \times h]$ . As below, we thus still get that  $\pi[g] \in \mathcal{N}$ . Now work in  $V[h]$ , where we have full  $<\theta$ -closure of  $\mathcal{N}$ .

Since  $\pi(\mathbb{P})$  is directed, there is a condition  $q \leq \pi[g]$  in  $\pi(\mathbb{P})$ . Using the fact that  $|\mathcal{N}| = \theta$  and  $\pi(\mathbb{P})$  is  $<\theta$ -closed, we can construct a  $\pi(\mathbb{P})$ -generic filter

$\tilde{g}$  over  $\mathcal{N}$  with  $q \in g$ . Namely, enumerate the dense subsets of  $\pi(\mathbb{P})$  that are elements of  $\mathcal{N}$  in order type  $\theta$  and use the fact that the initial segments of the sequence, and of the corresponding sequence of conditions that we construct, are in  $\mathcal{N}$ . Then  $\tilde{g}$  is as required.  $\dashv$

Since we now have that  $\pi[g] \subseteq \tilde{g}$  by the claim, the lifting criterion implies that we can lift  $\pi$  to  $\tilde{\pi}: H_\theta^V[g] \rightarrow \mathcal{N}[\tilde{g}]$ .

It thus remains to see that  $\mathcal{N}[\tilde{g}]$  is  $<\theta$ -closed. To see this, take a sequence  $\vec{x} = \langle x_i \mid i < \gamma \rangle$  with  $\gamma < \theta$  and  $x_i \in \mathcal{N}[\tilde{g}]$  and find names  $\sigma_i \in \mathcal{N}$  with  $\sigma_i^{\tilde{g}} = x_i$  for all  $i < \gamma$ . Since  $<^\theta \mathcal{N} \subseteq \mathcal{N}$  we have that  $\vec{\sigma} = \langle \sigma_i \mid i < \gamma \rangle \in \mathcal{N}$ , and from  $\vec{\sigma}$  we obtain a canonical name  $\vec{\sigma}^\bullet \in \mathcal{N}$  with  $\vec{\sigma}^{\bullet\tilde{g}} = \vec{x} \in \mathcal{N}[\tilde{g}]$ .  $\blacksquare$

Investigating further, we also show indestructibility for some forcings that do not fall into the above-mentioned categories.

**PROPOSITION 2.60** (N.-Schlicht). *Generic setwise supercompactness of a regular cardinal  $\kappa$  is indestructible for  $\text{Add}(\omega, \kappa)$ . If  $\kappa$  is a successor cardinal then it is also indestructible for  $\text{Col}(\omega, <\kappa)$ .*

**PROOF.** Let  $g$  be  $\text{Add}(\omega, \kappa)$ -generic over  $V$ . In  $V$  fix a regular  $\theta > \kappa$  and let  $\mathbb{Q}$  be the forcing given by the definition of generic setwise supercompactness. Let  $h$  be  $\mathbb{Q}$ -generic over  $V[g]$  and work in  $V[g \times h]$ .

Let  $\pi: H_\theta^V \rightarrow \mathcal{N}$  be as in the definition of generically setwise supercompactness. Moreover, let  $\tilde{g}$  be  $\text{Add}(\omega, \pi(\kappa))$ -generic over  $V[g \times h]$ . Since  $\pi[g] = g$ , the lifting criterion allows us to extend  $\pi$  to some  $\tilde{\pi}: H_\theta^V[g] \rightarrow \mathcal{N}[g \times \tilde{g}]$ . To show that  $\mathcal{N}[g \times \tilde{g}]$  is  $<\theta$ -closed in  $V[g \times h \times \tilde{g}]$ , it suffices that  $\text{Add}(\omega, \pi(\kappa))$  has the ccc by Lemma 1.54.

For  $\text{Col}(\omega, <\kappa)$ , we proceed similarly. Assume that  $\kappa = \nu^+$ . Take  $\text{Col}(\omega, <\kappa)$ -,  $\mathbb{Q}$ - and  $\text{Col}(\omega, <\pi(\kappa))$ -generic filters  $g$ ,  $h$  and  $\tilde{g}$ .  $\pi$  and  $\mathcal{N}$  are as above. Since  $\nu < \kappa < \theta < \pi(\kappa)$  and there are no cardinals between  $\nu$  and  $\pi(\kappa)$  (in  $\mathcal{N}$  and thus also in  $V[h]$ ),  $<\theta$ -closure means  $\nu$ -closure (in any model containing  $V[h]$ ). By Lemma 1.54, it is thus sufficient to know that  $\text{Col}(\omega, <\pi(\kappa))$  has the  $\nu^+$ -cc in  $V[g \times h]$ . This is because  $\pi(\kappa) = \nu^{+\mathcal{N}} \leq \nu^{+V[g \times h]}$ .  $\blacksquare$

Usuba's Theorem 2.56 shows that the *consistency strength* of these generically setwise supercompact cardinals is small, but do they appear naturally anywhere? The following result shows that we cannot find any in either  $L$ ,  $L[\mu]$  nor  $K$  below a measurable cardinal:

**PROPOSITION 2.61** (N.-Schlicht). *No cardinal  $\kappa$  is generically setwise supercompact in either  $L$ ,  $K$  below a measurable cardinal, or  $L[\mu]$  with  $\mu$  being a normal ultrafilter.*

PROOF. Assume first that  $V = L$  and that  $\kappa$  is generically setwise supercompact. Let  $g$  be a generic filter and  $\pi: L_\theta \rightarrow \mathcal{N}$  an embedding in  $V[g]$  with  $\pi \restriction L_{\kappa+L} \in \mathcal{N}$ . Then  $\mathcal{N} = L_\alpha$  for some  $\alpha$  by condensation and thus  $\pi \restriction H_{\kappa+L} \in L$ . But this would induce a  $<\kappa$ -complete ultrafilter on  $\kappa$ , contradicting  $V = L$ .

Assume now that there exists no inner model with a measurable cardinal and let  $K$  be the core model. Let  $\kappa$  be generically setwise supercompact in  $K$  and  $\pi: K|\theta \rightarrow \mathcal{N}$  be the generic elementary embedding. As above we get that

$$\pi \restriction H_{\kappa+K} \in \mathcal{N},$$

so that again  $\mathcal{N}$  has a measure on  $\kappa$ . But that means that  $K|\kappa$  has a measurable cardinal, which is a contradiction since  $\kappa$  is inaccessible (in both  $V$  and  $K$ ) and therefore  $K|\kappa \models \text{ZFC}$ , contradicting our assumption that no inner model with a measurable cardinal exists.

Assume now that  $V = L[\mu]$  and that  $\kappa$  is generically setwise supercompact, witnessed by a generic embedding  $\pi: L_\theta[\mu] \rightarrow L_\alpha[\bar{\mu}]$ . In particular this means that  $\pi \restriction L_{\kappa+L[\mu]}[\mu] \in L_\alpha[\bar{\mu}]$ . If  $\text{crit } \mu < \kappa$  then  $\mu = \bar{\mu}$  and

$$\mathcal{P}^{L[\mu]}(\kappa) = \mathcal{P}^{L[\bar{\mu}]}(\kappa),$$

so that both  $\pi(\kappa)$  and  $\kappa$  are now measurable cardinals in  $L[\bar{\mu}]$ , contradicting Solovay's Lemma [Kanamori, 2008, 20.2]. So  $\text{crit } \mu \geq \kappa$ .

If  $\pi(\text{crit } \mu) > \text{crit } \mu$  then by Kunen's Theorem [Kanamori, 2008, 20.12] we get that  $L[\bar{\mu}]$  is an iterate of  $L[\mu]$ . But iteration embeddings preserve the subsets of their critical point, so again we have that  $\mathcal{P}^{L[\mu]}(\kappa) = \mathcal{P}^{L[\bar{\mu}]}(\kappa)$  and we get the same contradiction as before.

Lastly, if  $\text{crit } \mu > \kappa$  and  $\pi(\text{crit } \mu) = \text{crit } \mu$  then  $\mu = \bar{\mu}$  by Kunen's Theorem [Kanamori, 2008, 20.10], so we get a contradiction as in the  $\text{crit } \mu < \kappa$  case. ■

### 3 | FILTERS & GAMES

Moving away from the pure theory of the virtual large cardinals from Chapter 2, we now move to connections between these large cardinals and common set-theoretic objects of study. In this chapter those objects are filters and games, with the next chapter dealing with connections to ideals. This chapter covers the content of the paper [Nielsen and Welch, 2019], which started out as a further analysis of the results in [Holy and Schlicht, 2018] and somewhat surprisingly we ended up in the realm of virtual large cardinals. In the process, we answer almost every open question raised in [Holy and Schlicht, 2018].

We will in this section be dealing with many properties of  $\mathcal{M}$ -measures<sup>1</sup>, so we start with a couple of definitions.

**DEFINITION 3.1.** Let  $\kappa$  be a cardinal,  $\mathcal{M}$  a weak  $\kappa$ -model and  $\mu$  an  $\mathcal{M}$ -measure. Then  $\mu$  is...

- **$\mathcal{M}$ -normal** if  $(\mathcal{M}, \in, \mu) \models \forall \vec{X} \in {}^\kappa \mu : \Delta \vec{X} \in \mu$ ;
- **genuine** if  $|\Delta \vec{X}| = \kappa$  for every  $\kappa$ -sequence  $\vec{X} \in {}^\kappa \mu$ ;
- **normal** if  $\Delta \vec{X}$  is stationary in  $\kappa$  for every  $\kappa$ -sequence  $\vec{X} \in {}^\kappa \mu$ ;
- **0-good**, or simply **good**, if it has a well-founded ultrapower when applied to  $\mathcal{M}$ ;
- **$\alpha$ -good** for  $\alpha > 0$  if it is weakly amenable and has  $\alpha$ -many well-founded iterated ultrapowers when applied to  $\mathcal{M}$ . ◦

We emphasise that the main difference between  $\mathcal{M}$ -normality and normality (and genuineness) is that the former is *local* and the latter are *global*.

We note a few basic relations between these properties.

**PROPOSITION 3.2.** Let  $\kappa$  be an uncountable cardinal,  $\mathcal{M}$  a weak  $\kappa$ -model. Then

- (i) Every genuine  $\mathcal{M}$ -measure on  $\kappa$  is countably complete;

---

<sup>1</sup>See Section 1.1 for the definitions of weak  $\kappa$ -models  $\mathcal{M}$  and their associated  $\mathcal{M}$ -measures.

(ii) Every countably complete weakly amenable  $\mathcal{M}$ -measure on  $\kappa$  is  $\alpha$ -good for all ordinals  $\alpha$ .

PROOF. (i): Let  $\mu$  be a genuine  $\mathcal{M}$ -measure on  $\kappa$ . To show countable completeness, let  $\vec{X} \in {}^\omega \mu$  be an  $\omega$ -sequence of measure one sets and define a  $\kappa$ -sequence  $\vec{Y} \in {}^\kappa \mu$  as  $Y_n := X_n$  for  $n < \omega$  and  $Y_\alpha := \kappa$  for  $\alpha \in [\omega, \kappa)$ . Then  $|\Delta \vec{Y}| = \kappa$  as  $\mu$  is genuine, so letting  $\alpha \in \Delta \vec{Y} - \omega$  we get that  $\alpha \in \bigcap \vec{X}$ , making  $\mu$  countably complete.

(ii): Now let  $\mu$  be a countably complete weakly amenable  $\mathcal{M}$ -measure on  $\kappa$ . Firstly note that countable completeness implies that the ultrapower  $\text{Ult}(\mathcal{M}, \mu)$  is well-founded. Next, weak amenability implies that  $X := \{\alpha < \kappa \mid X_\alpha \in \mu\} \in \mathcal{M}$  for every  $\vec{X} \in {}^\kappa \mu \cap \mathcal{M}$  since we can rewrite the set as

$$X = \{\alpha < \kappa \mid X_\alpha \in \{X_\beta \mid \beta < \kappa\} \cap \mu\}$$

and weak amenability ensures that  $\{X_\alpha \mid \alpha < \kappa\} \cap \mu \in \mathcal{M}$ . From this we can form iterated ultrapowers as in Chapter 19 of [Kanamori, 2008], which will all be well-founded by countable completeness of the measure. ■

Holy and Schlicht provided the following characterisation of the normal measures:

**LEMMA 3.3** ([Holy and Schlicht, 2018]). *Let  $\mathcal{M}$  be a weak  $\kappa$ -model and  $\mu$  an  $\mathcal{M}$ -measure. Then  $\mu$  is normal iff  $\Delta \vec{X}$  is stationary for some enumeration  $\vec{X}$  of  $\mu$ .*

PROOF. ( $\Rightarrow$ ) is trivial since  $|\vec{X}| = |\mu| \leq |\mathcal{M}| = \kappa$ , so assume that  $\vec{X}$  is an enumeration of  $\mu$  such that  $\Delta \vec{X}$  is stationary. Let  $\vec{Y} \in {}^\kappa \mu$  be a  $\kappa$ -sequence and define  $g: \kappa \rightarrow \kappa$  such that  $Y_\alpha = X_{g(\alpha)}$  for  $\alpha < \kappa$ . Letting  $C_g \subseteq \kappa$  be the club of closure points of  $g$  we get that  $\Delta \vec{X} \cap C_g \subseteq \Delta \vec{Y} \cap C_g$ , making  $\Delta \vec{Y}$  stationary. ■

We next move on to the games. All of our games will be two-player games with perfect information; see e.g. [Kanamori, 2008, Chapter 27] for an introduction to set-theoretic game theory. We will also, mostly for convenience, use the following *game equivalence* notion:

**DEFINITION 3.4.** Two games  $\mathcal{G}_0$  and  $\mathcal{G}_1$  are said to be **game equivalent**, or simply **equivalent**, if player I has a winning strategy in  $\mathcal{G}_0$  iff they have one in  $\mathcal{G}_1$ , and player II has a winning strategy in  $\mathcal{G}_0$  iff they have one in  $\mathcal{G}_1$ . We will also denote such an equivalence as  $\mathcal{G}_0 \sim \mathcal{G}_1$ .  $\circ$

The following is a game which was introduced by Holy and Schlicht and led to their notion of  $\alpha$ -Ramsey cardinals:

**DEFINITION 3.5** ([Holy and Schlicht, 2018]). For an uncountable cardinal  $\kappa = \kappa^{<\kappa}$ , a regular cardinal  $\gamma \leq \kappa$  and a regular cardinal  $\theta > \kappa$  define the game  $wfG_\gamma^\theta(\kappa)$  of length  $\gamma$  as follows.

$$\begin{array}{ccccccc} \text{I} & \mathcal{M}_0 & & \mathcal{M}_1 & & \mathcal{M}_2 & \cdots \\ \text{II} & & \mu_0 & & \mu_1 & & \mu_2 & \cdots \end{array}$$

Here  $\mathcal{M}_\alpha \prec H_\theta$  is a  $\kappa$ -model and  $\mu_\alpha$  is an  $\mathcal{M}_\alpha$ -measure, the  $\mathcal{M}_\alpha$ 's and  $\mu_\alpha$ 's are  $\subseteq$ -increasing and  $\langle \mathcal{M}_\xi \mid \xi < \alpha \rangle, \langle \mu_\xi \mid \xi < \alpha \rangle \in \mathcal{M}_\alpha$  for every  $\alpha < \gamma$ . Letting  $\mu := \bigcup_{\alpha < \gamma} \mu_\alpha$  and  $\mathcal{M} := \bigcup_{\alpha < \gamma} \mathcal{M}_\alpha$ , player II wins iff  $\mu$  is an  $\mathcal{M}$ -normal good  $\mathcal{M}$ -measure.  $\circ$

We will also be using the following fact due to Holy and Schlicht, that the games  $wfG_\gamma^\theta(\kappa)$  do not depend upon the values of  $\theta$ :

**LEMMA 3.6** ([Holy and Schlicht, 2018] 3.3). *For a fixed  $\kappa$  and  $\gamma$ ,  $wfG_\gamma^{\theta_0}(\kappa)$  and  $wfG_\gamma^{\theta_1}(\kappa)$  are equivalent for any regular  $\theta_0, \theta_1 > \kappa$ .*  $\blacksquare$

See the proof of Proposition 3.8 below for an idea of the proof strategy of this lemma.

We will be working with the following variant of the  $wfG_\gamma(\kappa)$  games in which we require less of player I and more of player II. It will turn out that this change of game is innocuous, as Proposition 3.12 will show that they are (game) equivalent:

**DEFINITION 3.7** (Holy-N.-Schlicht). Let  $\kappa = \kappa^{<\kappa}$  be an uncountable cardinal,  $\gamma \leq \kappa$  and  $\zeta$  ordinals and  $\theta > \kappa$  a regular cardinal. Then define the following **filter game**

$\mathcal{G}_\gamma^\theta(\kappa, \zeta)$  with  $(\gamma+1)$ -many rounds:

$$\begin{array}{ccccccc} \text{I} & \mathcal{M}_0 & & \mathcal{M}_1 & & \cdots & & \mathcal{M}_\gamma \\ \text{II} & & \mu_0 & & \mu_1 & & \cdots & & \mu_\gamma \end{array}$$

Here  $\mathcal{M}_\alpha \prec H_\theta$  is a weak  $\kappa$ -model for every  $\alpha \leq \gamma$ ,  $\mu_\alpha$  is a normal  $\mathcal{M}_\alpha$ -measure for  $\alpha < \gamma$ ,  $\mu_\gamma$  is an  $\mathcal{M}_\gamma$ -normal good  $\mathcal{M}_\gamma$ -measure and the  $\mathcal{M}_\alpha$ 's and  $\mu_\alpha$ 's are  $\subseteq$ -increasing. For limit ordinals  $\alpha \leq \gamma$  we furthermore require that  $\mathcal{M}_\alpha = \bigcup_{\xi < \alpha} \mathcal{M}_\xi$ ,  $\mu_\alpha = \bigcup_{\xi < \alpha} \mu_\xi$  and that  $\mu_\alpha$  is  $\zeta$ -good. Player II wins iff they could continue to play throughout all  $(\gamma+1)$ -many rounds.  $\circ$

Note that we assume that  $\kappa = \kappa^{<\kappa}$  is uncountable in the definition of the games that we are considering, so this is a standing assumption throughout this chapter, whenever any one of the above two games are considered.

As in Lemma 3.6, we do not have to worry about the  $\theta$  parameter. The proof is almost identical to the proof of Lemma 3.6, but we supply it here for completeness.

**PROPOSITION 3.8** ([Holy and Schlicht, 2018]).  $\mathcal{G}_\gamma^{\theta_0}(\kappa) \sim \mathcal{G}_\gamma^{\theta_1}(\kappa)$  for all regular cardinals  $\theta_0, \theta_1 > \kappa$ .

PROOF. Fix regular cardinals  $\theta_0, \theta_1 > \kappa$ . First assume that player I has a winning strategy  $\sigma_0$  in  $\mathcal{G}_\gamma^{\theta_0}(\kappa)$ ; we will informally describe a winning strategy  $\sigma_1$  for player I in  $\mathcal{G}_\gamma^{\theta_1}(\kappa)$ . Whenever  $\sigma_0$  plays a weak  $\kappa$ -model  $\mathcal{M}_\alpha \prec H_{\theta_0}$  we simply let  $\sigma_1$  play

$$\widetilde{\mathcal{M}}_\alpha := \text{Hull}^{H_{\theta_1}}(\mathcal{P}^{\mathcal{M}}(\kappa) \cup \bigcup_{\xi < \alpha} \widetilde{\mathcal{M}}_\xi),$$

which is by definition an elementary substructure of  $H_{\theta_1}$ . Then any response from player II in  $\mathcal{G}_\gamma^{\theta_1}(\kappa)$  is also a valid response in  $\mathcal{G}_\gamma^{\theta_0}(\kappa)$ , as  $\mathcal{P}^{\mathcal{M}_\alpha}(\kappa) \subseteq \mathcal{P}^{\widetilde{\mathcal{M}}_\alpha}(\kappa)$ , so  $\sigma_1$  is well-defined. Further, as  $\sigma_0$  is winning for player I, we get that  $\mu_\gamma$ , the last measure played by player II in  $\mathcal{G}_\gamma^{\theta_0}(\kappa)$ , does not have a well-founded ultrapower when applied to  $\mathcal{M}_\gamma$ . This is witnessed by an  $\omega$ -sequence  $\langle f_n \mid n < \omega \rangle$  of functions  $f_n: \kappa \rightarrow \kappa$  in  $\mathcal{M}_\gamma$  such that

$$\{\alpha < \kappa \mid f_{n+1}(\alpha) \in f_n(\alpha)\} \in \mu_\gamma.$$

These  $f_n$ 's can be encoded as subsets of  $\kappa$ , so that  $f_n \in \widetilde{\mathcal{M}}_\gamma$  as well, meaning that  $\mu_\gamma$  does not have a well-founded ultrapower when applied to  $\widetilde{\mathcal{M}}_\gamma$  either.

Next, assume that player II has a winning strategy  $\tau_0$  in  $\mathcal{G}_\gamma^{\theta_0}(\kappa)$ ; again we describe a winning strategy  $\tau_1$  for player II in  $\mathcal{G}_\gamma^{\theta_1}(\kappa)$ . Here, every time player I plays some  $\mathcal{M}$  in  $\mathcal{G}_\gamma^{\theta_1}(\kappa)$  we form  $\widetilde{\mathcal{M}} \prec H_{\theta_0}$  as above and let  $\tau_1$ 's response to  $\mathcal{M}$  be  $\tau_0$ 's response to  $\widetilde{\mathcal{M}}$ . Since  $\tau_0$ 's measures have well-founded ultrapowers when applied to the  $\widetilde{\mathcal{M}}_\gamma$ 's, they will also have well-founded ultrapowers when applied to the  $\mathcal{M}_\alpha$ 's, for the same reason as above. ■

We will for convenience write  $\mathcal{G}_\gamma^\theta(\kappa)$  for the game  $\mathcal{G}_\gamma^\theta(\kappa, 0)$ , and with the above Proposition 3.8 in mind we will also write  $\mathcal{G}_\gamma(\kappa)$  for  $\mathcal{G}_\gamma^\theta(\kappa)$ .

We will at times work with the following weakening of the filter game:

**DEFINITION 3.9 (N.).** Define the **weak filter game**  $\mathcal{G}_\gamma^-(\kappa, \zeta)$  like  $\mathcal{G}_\gamma^{\kappa^+}(\kappa, \zeta)$ , but where we do not require that  $\mu_\gamma$  is  $\zeta$ -good. ◻

We will also be working with the following variant of these games:

**DEFINITION 3.10 (N.).** Define the **Cohen game**  $\mathcal{C}_\gamma^\theta(\kappa)$  as  $\mathcal{G}_\gamma^\theta(\kappa)$  but where we require that  $|\mathcal{M}_\alpha - H_\kappa| < \gamma$  for every  $\alpha < \gamma$ , i.e. that we only allow player I to add  $< \gamma$  new elements to the models in each round, and where we only require  $\mathcal{M}_\alpha \models \text{ZFC}^-$  and  $\mathcal{M}_\alpha \prec H_\theta$  for  $\alpha \leq \gamma$  limit.<sup>2</sup>

Also define the **weak Cohen game**  $\mathcal{C}_\gamma^-(\kappa)$  in analogy with  $\mathcal{G}_\gamma^-(\kappa)$ . ◻

**PROPOSITION 3.11 (N.).** Assume  $\gamma^{\aleph_0} = \gamma$  and let  $\kappa$  be regular. Then  $\mathcal{C}_\gamma^-(\kappa)$  is equivalent to  $\mathcal{C}_\gamma^\theta(\kappa)$  for all regular  $\theta > \kappa$ . In particular, if CH holds then  $\mathcal{C}_{\omega_1}^-(\kappa)$  is equivalent to  $\mathcal{C}_{\omega_1}^\theta(\kappa)$  for all regular  $\theta > \kappa$ .

**PROOF.** The assumption that  $\gamma^{\aleph_0} = \gamma$  allows us to ensure without loss of generality that  ${}^\omega \mathcal{M}_\alpha \subseteq \mathcal{M}_\gamma$  holds for all  $\alpha < \gamma$ : If player I has a winning strategy in  $\mathcal{C}_\gamma^\theta(\kappa)$  for some regular  $\theta > \kappa$  then they still win if we require that  ${}^\omega \mathcal{M}_\alpha \subseteq \mathcal{M}_\gamma$  (since they are only enlarging their models, making it even harder for player II to win),

---

<sup>2</sup> $\mathcal{C}_\omega^\theta(\kappa)$  is similar to the  $H(F, \lambda)$ -games in [Donder and Levinski, 1989].

in which case the final measure  $\mu_\gamma$  is countably complete and hence automatically has a well-founded ultrapower.

If player II has a winning strategy in  $\mathcal{C}_\gamma^-(\kappa)$  then they still win if player I plays  $\mathcal{M}_\alpha$  such that  ${}^\omega \mathcal{M}_\alpha \subseteq \mathcal{M}_\gamma$ , ensuring that  $\mu_\gamma$  has a well-founded ultrapower. ■

**PROPOSITION 3.12** (Holy-N.-Schlicht).  $\mathcal{G}_\gamma^\theta(\kappa)$ ,  $\mathcal{G}_\gamma^\theta(\kappa, 1)$  and  $wfG_\gamma^\theta(\kappa)$  are all game equivalent for all limit ordinals  $\gamma \leq \kappa$ , and  $\mathcal{G}_\gamma^\theta(\kappa, \zeta)$  is equivalent to  $\mathcal{G}_\gamma^\theta(\kappa)$  whenever  $\text{cof } \gamma > \omega$  and  $\zeta \in \text{On}$ .

**PROOF.** We start by showing the latter statement, so assume that  $\text{cof } \gamma > \omega$ . Consider now the auxilliary game, call it  $\mathcal{G}$ , which is exactly like  $\mathcal{G}_\gamma^\theta(\kappa, 0)$ , but where we also require that  ${}^\omega \mathcal{M}_\alpha \subseteq \mathcal{M}_{\alpha+1}$  and  $\langle \mathcal{M}_\xi \mid \xi \leq \alpha \rangle, \langle \mu_\xi \mid \xi \leq \alpha \rangle \in \mathcal{M}_{\alpha+1}$  for every  $\alpha < \gamma$ .

*Claim 3.13.*  $\mathcal{G}$  is equivalent to  $\mathcal{G}_\gamma^\theta(\kappa)$ .

**PROOF OF CLAIM.** If player I has a winning strategy in  $\mathcal{G}$  then they also have one in  $\mathcal{G}_\gamma^\theta(\kappa)$ , by doing exactly the same. Analogously, if player II has a winning strategy in  $\mathcal{G}_\gamma^\theta(\kappa)$  then they also have one in  $\mathcal{G}$ . If player I has a winning strategy  $\sigma$  in  $\mathcal{G}_\gamma^\theta(\kappa)$  then we can construct a winning strategy  $\sigma'$  in  $\mathcal{G}$ , which is defined as follows. Fix  $\alpha \leq \gamma$  and, writing  $\vec{\mathcal{M}}_\xi := \langle \mathcal{M}_\xi \mid \xi \leq \alpha \rangle$  and  $\vec{\mu}_\xi := \langle \mu_\xi \mid \xi \leq \alpha \rangle$ , we set

$$\sigma'(\langle \mathcal{M}_\xi, \mu_\xi \mid \xi \leq \alpha \rangle) := \text{Hull}^{H_\theta}(\sigma(\langle \mathcal{M}_\xi, \mu_\xi \mid \xi \leq \alpha \rangle) \cup {}^\omega \mathcal{M}_\alpha \cup \{\vec{\mathcal{M}}_\xi, \vec{\mu}_\xi\}),$$

i.e. that we are simply throwing the sequences into our models and making sure that we are still an elementary substructure of  $H_\theta$ . This new strategy  $\sigma'$  is clearly winning. Assuming now that  $\tau$  is a winning strategy for player II in  $\mathcal{G}$ , we define a winning strategy  $\tau'$  for player II in  $\mathcal{G}_\gamma^\theta(\kappa)$  by letting  $\tau'(\langle \mathcal{M}_\xi, \mu_\xi \mid \xi \leq \alpha \rangle)$  be the result of throwing in the appropriate sequences into the models  $\mathcal{M}_\xi$ , applying  $\tau$  to get a measure, and intersecting that measure with  $\mathcal{M}_\alpha$  to get an  $\mathcal{M}_\alpha$ -measure.  $\dashv$

Now, letting  $\mathcal{M}_\gamma$  be the final model of a play of  $\mathcal{G}$ ,  $\text{cof } \gamma > \omega$  implies that any  $\omega$ -sequence  $\vec{X} \in \mathcal{M}_\gamma$  really is a sequence of elements from some  $\mathcal{M}_\xi$  for  $\xi < \gamma$ , so that  $\vec{X} \in \mathcal{M}_{\xi+1}$  by definition of  $\mathcal{G}$ , making  $\mathcal{M}_\gamma$  closed under  $\omega$ -sequences and thus also  $\mu_\gamma$  countably complete. Since  $\gamma$  is a limit ordinal and the models contain the previous measures and models as elements, the proof of e.g. Theorem 5.6 in [Holy and Schlicht, 2018] shows that  $\mu_\gamma$  is also weakly amenable, making it  $\zeta$ -good for all ordinals  $\zeta$ .

Now we deal with the first statement, stating that  $\mathcal{G}_\gamma^\theta(\kappa)$ ,  $\mathcal{G}_\gamma^\theta(\kappa, 1)$  and  $wfG_\gamma^\theta(\kappa)$  are all game equivalent for all limit ordinals  $\gamma \leq \kappa$ . Fix a limit ordinal  $\gamma$ . Firstly  $\mathcal{G}_\gamma^\theta(\kappa)$  is equivalent to  $\mathcal{G}_\gamma^\theta(\kappa, 1)$  as above, since the proof of Theorem 5.6 in [Holy and Schlicht, 2018] shows that  $\mu_\gamma$  is weakly amenable when  $\gamma$  is a limit ordinal. So it remains to show that  $\mathcal{G}_\gamma^\theta(\kappa)$  is equivalent to  $wfG_\gamma^\theta(\kappa)$ . If player I has a winning strategy  $\sigma$  in  $wfG_\gamma^\theta(\kappa)$  then define a winning strategy  $\sigma'$  for player I in  $\mathcal{G}_\gamma^\theta(\kappa)$  as

$$\sigma'(\langle \mathcal{M}_\xi, \mu_\xi \mid \xi \leq \alpha \rangle) := \sigma(\langle \mathcal{M}_0, \mu_0 \rangle \hat{\ } \langle \mathcal{M}_{\xi+1}, \mu_{\xi+1} \mid \xi + 1 \leq \alpha \rangle)$$

and for limit ordinals  $\alpha \leq \gamma$  set  $\sigma'(\langle \mathcal{M}_\xi, \mu_\xi \mid \xi < \alpha \rangle) := \bigcup_{\xi < \alpha} \mathcal{M}_\xi$ ; i.e. they simply follow the same strategy as in  $wfG_\gamma^\theta(\kappa)$  but plug in unions at limit stages. Likewise, if player II had a winning strategy in  $\mathcal{G}_\gamma^\theta(\kappa)$  then they also have a winning strategy in  $wfG_\gamma^\theta(\kappa)$ , this time just by skipping the limit steps in  $\mathcal{G}_\gamma^\theta(\kappa)$ .

Now assume that player I has a winning strategy  $\sigma$  in  $\mathcal{G}_\gamma^\theta(\kappa)$  and that player I does *not* have a winning strategy in  $wfG_\gamma^\theta(\kappa)$ . Then define a strategy  $\sigma'$  for player I in  $wfG_\gamma^\theta(\kappa)$  as follows. Let  $s = \langle \mathcal{M}_\alpha, \mu_\alpha \mid \alpha \leq \eta \rangle$  be a partial play of  $wfG_\gamma^\theta(\kappa)$  and let  $s'$  be the modified version of  $s$  in which we have “inserted” unions at limit steps, just as in the above paragraph. We can assume that every  $\mu_\alpha$  in  $s'$  is good and  $\mathcal{M}_\alpha$ -normal as otherwise player II has already lost and player I can play anything. Now, we want to show that  $s'$  is a valid partial play of  $\mathcal{G}_\gamma^\theta(\kappa)$ . All the models in  $s$  are  $\kappa$ -models, so in particular weak  $\kappa$ -models.

*Claim 3.14.* Every  $\mu_\alpha$  in  $s'$  is normal.

PROOF OF CLAIM. Assume without loss of generality that  $\alpha = \eta$ . Let player I play any legal response  $\mathcal{M}$  to  $s$  in  $wfG_\gamma^\theta(\kappa)$  (such a response always exists). If player II cannot respond then player I has a winning strategy by simply following

$s^\cap \langle \mathcal{M} \rangle$ ,  $\not\leq$ , so player II *does* have a response  $\mu$  to  $s^\cap \mathcal{M}$ . But now the rules of  $wfG_\gamma^\theta(\kappa)$  ensure that  $\mu_\eta \in \mathcal{M}$ , so since

$$(\mathcal{M}, \in, \mu) \models \forall \vec{X} \in {}^\kappa \mu : \ulcorner \Delta \vec{X} \text{ is stationary in } \kappa^\top,$$

we then also get that  $\mathcal{M} \models \ulcorner \Delta \mu_\eta \text{ is stationary in } \kappa^\top$  since  $\mu_\eta \subseteq \mu$ , so elementarity of  $\mathcal{M}$  in  $H_\theta$  implies that  $\Delta \mu_\eta$  really *is* stationary in  $\kappa$ , making  $\mu_\eta$  normal.  $\dashv$

This makes  $s'$  a valid partial play of  $\mathcal{G}_\gamma^\theta(\kappa)$ , so we may form the weak  $\kappa$ -model  $\tilde{\mathcal{M}}_\eta := \sigma(s')$ . Now let  $\mathcal{M}_\eta \prec H_\theta$  be a  $\kappa$ -model with  $\tilde{\mathcal{M}}_\eta \subseteq \mathcal{M}_\eta$  and  $s \in \mathcal{M}_\eta$  and set  $\sigma'(s) := \mathcal{M}_\eta$ . This defines the strategy  $\sigma'$  for player I in  $wfG_\gamma^\theta(\kappa)$ , which is winning since the winning condition for the two games is the same for  $\gamma$  a limit. More precisely, that  $\sigma$  is winning in  $\mathcal{G}_\gamma^\theta(\kappa)$  means that there is a sequence

$$\langle f_n : \kappa \rightarrow \kappa \mid n < \omega \rangle$$

with the  $f_n$ 's all being elements of the last model  $\tilde{\mathcal{M}}_\gamma$ , witnessing the ill-foundedness of the ultrapower. But then all these functions will also be elements of the union of the  $\mathcal{M}_\alpha$ 's, since we ensured that  $\mathcal{M}_\alpha \supseteq \tilde{\mathcal{M}}_\alpha$  in the construction above, making the ultrapower of  $\bigcup_{\alpha < \gamma} \mathcal{M}_\alpha$  by  $\bigcup_{\alpha < \gamma} \mu_\alpha$  ill-founded as well.

Next, assume that player II has a winning strategy  $\tau$  in  $wfG_\gamma^\theta(\kappa)$ . We recursively define a strategy  $\tilde{\tau}$  for player II in  $\mathcal{G}_\gamma^\theta(\kappa)$  as follows. If  $\tilde{\mathcal{M}}_0$  is the first move by player I in  $\mathcal{G}_\gamma^\theta(\kappa)$ , let  $\mathcal{M}_0 \prec H_\theta$  be a  $\kappa$ -model with  $\tilde{\mathcal{M}}_0 \subseteq \mathcal{M}_0$ , making  $\mathcal{M}_0$  a valid move for player I in  $wfG_\gamma^\theta(\kappa)$ . Write  $\mu_0 := \tau(\langle \mathcal{M}_0 \rangle)$  and then set  $\tilde{\tau}(\langle \tilde{\mathcal{M}}_0 \rangle)$  to be  $\tilde{\mu}_0 := \mu_0 \cap \tilde{\mathcal{M}}_0$ , which again is normal by the same trick as above, making  $\tilde{\mu}_0$  a legal move for player II in  $\mathcal{G}_\gamma^\theta(\kappa)$ . Successor stages  $\alpha + 1$  in the construction are analogous, but we also make sure that  $\langle \mathcal{M}_\xi \mid \xi < \alpha + 1 \rangle, \langle \mu_\xi \mid \xi < \alpha + 1 \rangle \in \mathcal{M}_{\alpha+1}$ . At limit stages  $\tau$  outputs unions, as is required by the rules of  $\mathcal{G}_\gamma^\theta(\kappa)$ . Since the union of all the  $\mu_\alpha$ 's is good as  $\tau$  is winning,  $\tilde{\mu}_\gamma := \bigcup_{\alpha < \gamma} \tilde{\mu}_\alpha$  is good as well, making  $\tilde{\tau}$  winning and we are done.  $\blacksquare$

We now arrive at the definitions of the cardinals we will be considering. They were in [Holy and Schlicht, 2018] only defined for  $\gamma$  being a cardinal, but given the above result we generalise it to all ordinals  $\gamma$ .

**DEFINITION 3.15.** Let  $\kappa$  be a cardinal and  $\gamma \leq \kappa$  an ordinal. Then  $\kappa$  is  **$\gamma$ -Ramsey** if player I does not have a winning strategy in  $\mathcal{G}_\gamma^\theta(\kappa)$  for all regular  $\theta > \kappa$ . We furthermore say that  $\kappa$  is **strategic  $\gamma$ -Ramsey** if player II *does* have a winning strategy in  $\mathcal{G}_\gamma^\theta(\kappa)$  for all regular  $\theta > \kappa$ .

Define **(strategic) genuine  $\gamma$ -Ramseys** and **(strategic) normal  $\gamma$ -Ramseys** analogously, but where we require the last measure  $\mu_\gamma$  to be genuine and normal, respectively.  $\circ$

**DEFINITION 3.16 (N.).** A cardinal  $\kappa$  is  **$<\gamma$ -Ramsey** if it is  $\alpha$ -Ramsey for every  $\alpha < \gamma$ , **almost fully Ramsey** if it is  $<\kappa$ -Ramsey and **fully Ramsey** if it is  $\kappa$ -Ramsey.

Further, say that  $\kappa$  is **coherent  $<\gamma$ -Ramsey** if it is strategic  $\alpha$ -Ramsey for every  $\alpha < \gamma$  and that there exists a choice of winning strategies  $\tau_\alpha$  in  $\mathcal{G}_\alpha(\kappa)$  for player II satisfying that  $\tau_\alpha \subseteq \tau_\beta$  whenever  $\alpha < \beta$ . In other words, there is a single strategy  $\tau$  for player II in  $\mathcal{G}_\gamma(\kappa)$  such that  $\tau$  is a winning strategy for player II in  $\mathcal{G}_\alpha(\kappa)$  for every  $\alpha < \gamma$ , but we do not require  $\tau$  to be winning in  $\mathcal{G}_\gamma(\kappa)$ <sup>3</sup>.  $\circ$

This is not the original definition of (strategic)  $\gamma$ -Ramsey cardinals however, as this involved elementary embeddings between weak  $\kappa$ -models – but as the following theorem due to Holy and Schlicht shows, the two definitions coincide whenever  $\gamma$  is a regular cardinal:

**THEOREM 3.17** ([Holy and Schlicht, 2018]). *For regular cardinals  $\lambda$ , a cardinal  $\kappa$  is  $\lambda$ -Ramsey iff for arbitrarily large  $\theta > \kappa$  and every subset  $A \subseteq \kappa$  there is a weak  $\kappa$ -model  $\mathcal{M} \prec H_\theta$  with  $\mathcal{M}^{<\lambda} \subseteq \mathcal{M}$  and  $A \in \mathcal{M}$  with an  $\mathcal{M}$ -normal 1-good  $\mathcal{M}$ -measure  $\mu$  on  $\kappa$ .* ■

### 3.1 THE FINITE CASE

In this section we are going to consider properties of the  $n$ -Ramsey cardinals for finite  $n$ . Note in particular that the  $\mathcal{G}_n^\theta(\kappa)$  games are determined, making the “strategic” adjective superfluous in this case. We further note that the  $\theta$ ’s are also dispensable in this finite case:

<sup>3</sup>Note that, with this terminology, “coherent” is a stronger notion than “strategic”. We could have called the cardinals *coherent strategic  $<\gamma$ -Ramseys*, but we opted for brevity instead.

**PROPOSITION 3.18 (N).** *Let  $\kappa < \theta$  be regular cardinals and  $n < \omega$ . Then player II has a winning strategy in  $\mathcal{G}_n^\theta(\kappa)$  iff they have a winning strategy in the game  $\mathcal{G}_n(\kappa)$ , which is defined as  $\mathcal{G}_n^\theta(\kappa)$  except that we do not require that  $\mathcal{M}_n \prec H_\theta$ .*

**PROOF.**  $\Leftarrow$  is clear, so assume that II has a winning strategy  $\tau$  in  $\mathcal{G}_n^\theta(\kappa)$ . Whenever player I plays  $\mathcal{M}_k$  in  $\mathcal{G}_n(\kappa)$  for  $k \leq n$  then define  $\mathcal{M}_k^* := \text{Hull}^{H_\theta}(\mathcal{P})$ , where  $\mathcal{P} \cong \mathcal{M}_k$  is the transitive collapse of  $\mathcal{M}_k$ , and play  $\mathcal{M}_k^*$  in  $\mathcal{G}_n^\theta(\kappa)$ . Let  $\mu_k$  be the  $\tau$ -responses to the  $\mathcal{M}_k^*$ 's and let player II play the  $\mu_k$ 's in  $\mathcal{G}_n(\kappa)$  as well.

Assume that this new strategy is not winning for player II in  $\mathcal{G}_n(\kappa)$ , so that  $\text{Ult}(\mathcal{M}_n, \mu_n)$  is ill-founded. This is witnessed by some  $\vec{f} := \langle f_k \mid k < \omega \rangle$  of  $f_k \in {}^\kappa o(\mathcal{M}_n) \cap \mathcal{M}_n$  with  $X_k := \{\alpha < \kappa \mid f_{k+1}(\alpha) < f_k(\alpha)\} \in \mu_n$  for all  $k < \omega$ . Let  $\nu \gg \kappa$ ,  $\mathcal{H} := \text{cHull}^{H_\nu}(\mathcal{M}_n \cup \{\vec{f}, \mathcal{M}_n, \mu_n\})$  be the transitive collapse of the Skolem hull  $\text{Hull}^{H_\nu}(\mathcal{M}_n \cup \{\vec{f}, \mathcal{M}_n, \mu_n\})$ , and  $\pi : \mathcal{H} \rightarrow H_\nu$  be the uncollapse; write  $\bar{x} := \pi^{-1}(x)$  for all  $x \in \text{ran } \pi$ .

Now  $\bar{A} = A$  for every  $A \in \mathcal{P}(\kappa) \cap \mathcal{M}_n$  and thus also  $\bar{\mu}_n = \mu_n$ . But now the  $\bar{f}_k$ 's witness that  $\text{Ult}(\bar{\mathcal{M}}_n, \bar{\mu}_n)$  is ill-founded and thus also that  $\text{Ult}(\mathcal{M}_n^*, \mu_n)$  is ill-founded since  $\mathcal{M}_n^* = \text{Hull}^{H_\theta}(\bar{\mathcal{M}}_n)$ , contradicting that  $\tau$  is winning. ■

For this reason we will work with the  $\mathcal{G}_n(\kappa)$  games throughout this section. Since we do not have to deal with the  $\theta$ 's anymore we note that  $n$ -Ramseyness can now be described using a  $\Pi_{2n+2}^1$ -formula and normal  $n$ -Ramseyness using a  $\Pi_{2n+3}^1$ -formula.

We have the following characterisations:

**THEOREM 3.19** ([Abramson et al., 1977]). *Let  $\kappa = \kappa^{<\kappa}$  be a cardinal. Then*

- (i)  $\kappa$  is weakly compact if and only if it is 0-Ramsey;
- (ii)  $\kappa$  is weakly ineffable if and only if it is genuine 0-Ramsey;
- (iii)  $\kappa$  is ineffable if and only if it is normal 0-Ramsey.

**PROOF.** This is mostly just changing the terminology in [Abramson et al., 1977] to the current game-theoretic one, so we only show (i).

Theorem 1.1.3 in [Abramson et al., 1977] shows that  $\kappa$  is weakly compact if and only if every  $\kappa$ -sized collection of subsets of  $\kappa$  is measured by a  $<\kappa$ -complete

measure, in the sense that every  $<\kappa$ -sequence (in  $V$ ) of measure one sets has a non-empty intersection.

For the  $\Rightarrow$  direction we can let player II respond to any  $\mathcal{M}_0$  by first getting the  $<\kappa$ -complete  $\mathcal{M}_0$ -measure  $\nu_0$  on  $\kappa$  from the above-mentioned result, forming the (well-founded) ultrapower  $\pi : \mathcal{M}_0 \rightarrow \text{Ult}(\mathcal{M}_0, \nu)$  and then playing the derived measure of  $\pi$ , which is  $\mathcal{M}_0$ -normal and good. For  $\Leftarrow$ , if  $X \subseteq \mathcal{P}(\kappa)$  has size  $\kappa$  then, using that  $\kappa = \kappa^{<\kappa}$ , we can find a  $\kappa$ -model  $\mathcal{M}_0 \prec H_\theta$  with  $X \subseteq \mathcal{M}_0$ . Letting player I play  $\mathcal{M}_0$  in  $\mathcal{G}_0(\kappa)$  we get some  $\mathcal{M}_0$ -normal good  $\mathcal{M}_0$ -measure  $\mu_0$  on  $\kappa$ . Since  $\mathcal{M}_0$  is closed under  $<\kappa$ -sequences we get that  $\mu_0$  is  $<\kappa$ -complete. ■

### 3.1.1 Indescribability

In this section we aim to prove that  $n$ -Ramseys are  $\Pi_{2n+1}^1$ -indescribable and that normal  $n$ -Ramseys are  $\Pi_{2n+2}^1$ -indescribable, which will also establish that the hierarchy of alternating  $n$ -Ramseys and normal  $n$ -Ramseys forms a strict hierarchy. Recall the following definition:

**DEFINITION 3.20.** A cardinal  $\kappa$  is  $\Pi_n^1$ -**indescribable** if whenever  $\varphi(v)$  is a  $\Pi_n$  formula,  $X \subseteq V_\kappa$  and  $V_{\kappa+1} \models \varphi[X]$ , then there is an ordinal  $\alpha < \kappa$  such that  $V_{\alpha+1} \models \varphi[X \cap V_\alpha]$ . ◦

Our first indescribability result is then the following, where the  $n = 0$  case is inspired by the proof of weakly compact cardinals being  $\Pi_1^1$ -indescribable – see [Abramson et al., 1977].

**THEOREM 3.21 (N.).** *Every  $n$ -Ramsey  $\kappa$  is  $\Pi_{2n+1}^1$ -indescribable for  $n < \omega$ .*

**PROOF.** Let  $\kappa$  be  $n$ -Ramsey and assume that it is not  $\Pi_{2n+1}^1$ -indescribable, witnessed by a  $\Pi_{2n+1}^1$ -formula  $\varphi(v)$  and a subset  $X \subseteq V_\kappa$ , meaning that  $V_{\kappa+1} \models \varphi[X]$  and, for every  $\alpha < \kappa$ ,  $V_{\alpha+1} \models \neg\varphi[X \cap V_\alpha]$ . We will deal with the  $(2n+1)$ -many quantifiers occurring in  $\varphi$  in  $(n+1)$ -many steps. We will here describe the first two steps with the remaining steps following the same pattern.

**First step.** Write  $\varphi(v) \equiv \forall v_1 \psi(v, v_1)$  for a  $\Sigma_{2n}$ -formula  $\psi(v, v_1)$ . As we are assuming that  $V_{\alpha+1} \models \neg\varphi[X \cap V_\alpha]$  holds for every  $\alpha < \kappa$ , we can pick witnesses  $A_\alpha^{(0)} \subseteq V_\alpha$  to the outermost existential quantifier in  $\neg\varphi[X \cap V_\alpha]$ .

Let  $\mathcal{M}_0$  be a weak  $\kappa$ -model such that  $V_\kappa \subseteq \mathcal{M}_0$  and  $\vec{A}^{(0)}, X \in \mathcal{M}_0$ . Fix a good  $\mathcal{M}_0$ -normal  $\mathcal{M}_0$ -measure  $\mu_0$  on  $\kappa$ , using the 0-Ramseyess of  $\kappa$ . Form  $\mathcal{A}^{(0)} := [\vec{A}^{(0)}]_{\mu_0} \in \text{Ult}(\mathcal{M}_0, \mu_0)$ , where we without loss of generality may assume that the ultrapower is transitive.  $\mathcal{M}_0$ -normality of  $\mu_0$  implies that  $\mathcal{A}^{(0)} \subseteq V_\kappa$ , so that we have that  $V_{\kappa+1} \models \psi[X, \mathcal{A}^{(0)}]$ . Now Loś' Lemma,  $\mathcal{M}_0$ -normality of  $\mu_0$  and  $V_\kappa \subseteq \mathcal{M}_0$  also ensures that

$$\text{Ult}(\mathcal{M}_0, \mu_0) \models \ulcorner V_{\kappa+1} \models \neg\psi[X, \mathcal{A}^{(0)}] \urcorner. \quad (1)$$

This finishes the first step. Note that if  $n = 0$  then  $\neg\psi$  would be a  $\Delta_0$ -formula, so that (1) would be absolute to the true  $V_{\kappa+1}$ , yielding a contradiction. If  $n > 0$  we cannot yet conclude this however, but that is what we are aiming for in the remaining steps.

**Second step.** Write  $\psi(v, v_1) \equiv \exists v_2 \forall v_3 \chi(v, v_1, v_2, v_3)$  for a  $\Sigma_{2(n-1)}$ -formula  $\chi(v, v_1, v_2, v_3)$ . Since we have established that  $V_{\kappa+1} \models \psi[X, \mathcal{A}^{(0)}]$  we can pick some  $B^{(0)} \subseteq V_\kappa$  such that

$$V_{\kappa+1} \models \forall v_3 \chi[X, \mathcal{A}^{(0)}, B^{(0)}, v_3] \quad (2)$$

which then also means that, for every  $\alpha < \kappa$ ,

$$V_{\alpha+1} \models \exists v_3 \neg\chi[X \cap V_\alpha, A_\alpha^{(0)}, B^{(0)} \cap V_\alpha, v_3]. \quad (3)$$

Fix witnesses  $A_\alpha^{(1)} \subseteq V_\alpha$  to the existential quantifier in (3) and define the sets

$$S_\alpha^{(0)} := \{\xi < \kappa \mid A_\xi^{(0)} \cap V_\alpha = \mathcal{A}^{(0)} \cap V_\alpha\}$$

for every  $\alpha < \kappa$  and note that  $S_\alpha^{(0)} \in \mu_0$  for every  $\alpha < \kappa$ , since  $V_\kappa \subseteq \mathcal{M}_0$  ensures that  $\mathcal{A}^{(0)} \cap V_\alpha \in \mathcal{M}_0$  and  $\mathcal{M}_0$ -normality of  $\mu_0$  then implies that  $S_\alpha^{(0)} \in \mu_0$  is equivalent to

$$\text{Ult}(\mathcal{M}_0, \mu_0) \models \mathcal{A}^{(0)} \cap V_\alpha = \mathcal{A}^{(0)} \cap V_\alpha,$$

which is clearly the case. Now let  $\mathcal{M}_1 \supseteq \mathcal{M}_0$  be a weak  $\kappa$ -model such that  $\mathcal{A}^{(0)}, \vec{A}^{(1)}, \vec{S}^{(0)}, B^{(0)} \in \mathcal{M}_1$ . Let  $\mu_1 \supseteq \mu_0$  be an  $\mathcal{M}_1$ -normal  $\mathcal{M}_1$ -measure on  $\kappa$ , using the 1-Ramseyness of  $\kappa$ , so that  $\mathcal{M}_1$ -normality of  $\mu_1$  yields that  $\Delta \vec{S}^{(0)} \in \mu_1$ . Observe that  $\xi \in \Delta \vec{S}^{(0)}$  if and only if  $A_\xi^{(0)} \cap V_\alpha = \mathcal{A}^{(0)} \cap V_\alpha$  for every  $\alpha < \xi$ , so if  $\xi$  is a limit ordinal then it holds that  $A_\xi^{(0)} = \mathcal{A}^{(0)} \cap V_\xi$ . Now, as before, form  $\mathcal{A}^{(1)} := [\vec{A}^{(1)}]_{\mu_1} \in \text{Ult}(\mathcal{M}_1, \mu_1)$ , so that (2) implies that

$$V_{\kappa+1} \models \chi[X, \mathcal{A}^{(0)}, B^{(0)}, \mathcal{A}^{(1)}]$$

and the definition of the  $A_\alpha^{(1)}$ 's along with (3) gives that, for every  $\alpha < \kappa$ ,

$$V_{\alpha+1} \models \neg \chi[X \cap V_\alpha, A_\alpha^{(0)}, B^{(0)} \cap V_\alpha, A_\alpha^{(1)}].$$

Now this, paired with the above observation regarding  $\Delta \vec{S}^{(0)}$ , means that for every  $\alpha \in \Delta \vec{S}^{(0)} \cap \text{Lim}$  we have that

$$V_{\alpha+1} \models \neg \chi[X \cap V_\alpha, \mathcal{A}^{(0)} \cap V_\alpha, B^{(0)} \cap V_\alpha, A_\alpha^{(1)}],$$

so that  $\mathcal{M}_1$ -normality of  $\mu_1$  and Loś' lemma implies that

$$\text{Ult}(\mathcal{M}_1, \mu_1) \models \ulcorner V_{\kappa+1} \models \neg \chi[X, \mathcal{A}^{(0)}, B^{(0)}, \mathcal{A}^{(1)}] \urcorner.$$

This finishes the second step. Continue in this way for a total of  $(n+1)$ -many steps, ending with a  $\Delta_0$ -formula  $\phi(v, v_1, \dots, v_{2n+1})$  such that

$$V_{\kappa+1} \models \phi[X, \mathcal{A}^{(0)}, B^{(0)}, \dots, \mathcal{A}^{(n-1)}, B^{(n-1)}, \mathcal{A}^{(n)}] \quad (4)$$

and that  $\text{Ult}(\mathcal{M}_n, \mu_n) \models \ulcorner V_{\kappa+1} \models \neg \phi[X, \mathcal{A}^{(0)}, B^{(0)}, \dots, \mathcal{A}^{(n)}] \urcorner$ . But now absoluteness of  $\neg \phi$  means that  $V_{\kappa+1} \models \neg \phi[X, \mathcal{A}^{(0)}, B^{(0)}, \dots, \mathcal{A}^{(n)}]$ , which contradicts (4) above. ■

Note that this is optimal, as we saw that  $n$ -Ramseyness can be described by a  $\Pi_{2n+2}^1$ -formula. As a corollary we then immediately get the following:

**COROLLARY 3.22 (N.).** *Every  $<\omega$ -Ramsey cardinal is  $\Delta_0^2$ -indescribable.* ■

The second indescribability result concerns the normal  $n$ -Ramseys, where the  $n = 0$  case here is inspired by the proof of ineffable cardinals being  $\Pi_2^1$ -indescribable – see [Abramson et al., 1977].

**THEOREM 3.23 (N.).** *Every normal  $n$ -Ramsey  $\kappa$  is  $\Pi_{2n+2}^1$ -indescribable for  $n < \omega$ .*

Before we commence with the proof, note that we cannot simply do the same thing as we did in the proof of Theorem 3.21, as we would end up with a  $\Pi_1^1$  statement in an ultrapower, and as  $\Pi_1^1$  statements are not upwards absolute in general we would not be able to get our contradiction.

PROOF. Let  $\kappa$  be normal  $n$ -Ramsey and assume that it is not  $\Pi_{2n+2}^1$ -indescribable, witnessed by a  $\Pi_{2n+2}$ -formula  $\varphi(v)$  and a subset  $X \subseteq V_\kappa$ . Use that  $\kappa$  is  $n$ -Ramsey to perform the same  $n + 1$  steps as in the proof of Theorem 3.21. This gives us a  $\Sigma_1$ -formula  $\phi(v, v_1, \dots, v_{2n+1})$  along with sequences  $\langle \mathcal{A}^{(0)}, \dots, \mathcal{A}^{(n)} \rangle$ ,  $\langle B^{(0)}, \dots, B^{(n-1)} \rangle$  and a play  $\langle \mathcal{M}_k, \mu_k \mid k \leq n \rangle$  of  $\mathcal{G}_n(\kappa)$  in which player II wins and  $\mu_n$  is normal, such that

$$V_{\kappa+1} \models \phi[X, \mathcal{A}^{(0)}, B^{(0)}, \dots, \mathcal{A}^{(n-1)}, B^{(n-1)}, \mathcal{A}^{(n)}] \quad (1)$$

and, for  $\mu_n$ -many  $\alpha < \kappa$ ,

$$V_{\alpha+1} \models \neg \phi[X \cap V_\alpha, \mathcal{A}^{(0)} \cap V_\alpha, B^{(0)} \cap V_\alpha, \dots, \mathcal{A}^{(n-1)} \cap V_\alpha, B^{(n-1)} \cap V_\alpha, \mathcal{A}_\alpha^{(n)}].$$

Now form  $S_\alpha^{(n)} \in \mu_n$  as in the proof of Theorem 3.21. The main difference now is that we do not know if  $\vec{S}^{(n)} \in \mathcal{M}_n$  (in the proof of Theorem 3.21 we only ensured that  $\vec{S}^{(k)} \in \mathcal{M}_{k+1}$  for every  $k < n$  and we only defined  $\vec{S}^{(k)}$  for  $k < n$ ), but we can now use normality<sup>4</sup> of  $\mu_n$  to ensure that we *do* have that  $\triangle \vec{S}^{(n)}$  is stationary in  $\kappa$ . This means that we get a stationary set  $S \subseteq \kappa$  such that for every  $\alpha \in S$  it holds that

$$V_{\alpha+1} \models \neg \phi[X \cap V_\alpha, \mathcal{A}^{(0)} \cap V_\alpha, B^{(0)} \cap V_\alpha, \dots, B^{(n-1)} \cap V_\alpha, \mathcal{A}^{(n)} \cap V_\alpha]. \quad (2)$$

<sup>4</sup>Recall that this is stronger than just requiring it to be  $\mathcal{M}_n$ -normal – we do not require  $\vec{S}^{(n)} \in \mathcal{M}_n$ .

Now note that since  $\kappa$  is inaccessible it is  $\Sigma_1^1$ -indescribable, meaning that we can reflect (1). Furthermore, Lemma 3.4.3 of [Abramson et al., 1977] shows that the set of reflection points of  $\Sigma_1^1$ -formulas is in fact club, so intersecting this club with  $S$  we get a  $\zeta \in S$  satisfying that

$$V_{\zeta+1} \models \phi[X \cap V_\zeta, \mathcal{A}^{(0)} \cap V_\zeta, B^{(0)} \cap V_\zeta, \dots, B^{(n-1)} \cap V_\zeta, \mathcal{A}^{(n)} \cap V_\zeta],$$

contradicting (2). ■

Note that this is optimal as well, since we saw that normal  $n$ -Ramseyness can be described by a  $\Pi_{2n+3}^1$ -formula. In particular this then means that every  $(n+1)$ -Ramsey is a normal  $n$ -Ramsey stationary limit of normal  $n$ -Ramseys, and every normal  $n$ -Ramsey is an  $n$ -Ramsey stationary limit of  $n$ -Ramseys, making the hierarchy of alternating  $n$ -Ramseys and normal  $n$ -Ramseys a strict hierarchy.

### 3.1.2 Downwards absoluteness to $L$

Our absoluteness result below, Theorem 3.25, is inspired by several arguments in [Abramson et al., 1977], and uses the following lemma from that paper:

**LEMMA 3.24** ([Abramson et al., 1977]). *There is a  $\Pi_1^1$  formula  $\varphi(A)$  such that, for any ordinal  $\alpha$ ,  $(V_\alpha, V_{\alpha+1}) \models \varphi[A]$  iff  $\alpha$  is a regular cardinal and  $A$  is a non-constructible subset of  $\alpha$ .<sup>5</sup>* ■

**THEOREM 3.25** (N). *Genuine and normal  $n$ -Ramseys are downwards absolute to  $L$ , for every  $n < \omega$ .*

**PROOF.** Assume first that  $n = 0$  and that  $\kappa$  is a genuine 0-Ramsey cardinal. Let  $\mathcal{M} \in L$  be a weak  $\kappa$ -model – we want to find a genuine  $\mathcal{M}$ -measure inside  $L$ . By assumption we *can* find such a measure  $\mu$  in  $V$ ; we will show that in fact  $\mu \in L$ . Fix any enumeration  $\langle A_\xi \mid \xi < \kappa \rangle \in L$  of  $\mathcal{P}(\kappa) \cap \mathcal{M}$ . It then clearly suffices to show that  $T \in L$ , where  $T := \{\alpha < \kappa \mid A_\xi \in \mu\}$ .

*Claim 3.26.*  $T \cap \alpha \in L$  for any  $\alpha < \kappa$ .

---

<sup>5</sup>This appears as Lemma 4.1.2 in [Abramson et al., 1977].

PROOF OF CLAIM. Let  $\vec{B}$  be the  $\mu$ -positive part of  $\vec{A}$ , meaning that  $B_\xi := A_\xi$  if  $A_\xi \in \mu$  and  $B_\xi := \neg A_\xi$  if  $A_\xi \notin \mu$ . As  $\mu$  is genuine we get that  $\Delta \vec{B}$  has size  $\kappa$ , so we can pick  $\delta \in \Delta \vec{B}$  with  $\delta > \alpha$ . Then  $T \cap \alpha = \{\xi < \alpha \mid \delta \in A_\xi\}$ , which can be constructed within  $L$ .  $\dashv$

Now let  $\varphi$  be the  $\Pi_1^1$  formula given by Lemma 3.24. If we therefore assume that  $T \notin L$  then  $(V_\kappa, V_{\kappa+1}) \models \varphi[T]$ , which by  $\Pi_1^1$ -indescribability of  $\kappa$  means that there exists some  $\alpha < \kappa$  such that  $(V_\alpha, V_{\alpha+1}) \models \varphi[T \cap V_\alpha]$ , i.e. that  $T \cap \alpha \notin L$ , contradicting the claim. Therefore  $\mu \in L$ . It is still genuine in  $L$  as  $(\Delta \mu)^L = \Delta \mu$ , and if  $\mu$  was normal then that is still true in  $L$  as clubs in  $L$  are still clubs in  $V$ . The cases where  $\kappa$  is a genuine or normal  $n$ -Ramsey cardinal is analogous. ■

Since  $(n+1)$ -Ramseys are normal  $n$ -Ramseys we then immediately get the following:

**COROLLARY 3.27 (N).** *Every  $(n+1)$ -Ramsey cardinal is a normal  $n$ -Ramsey cardinal in  $L$ , for every  $n < \omega$ . In particular,  $<\omega$ -Ramseys are downwards absolute to  $L$ .* ■

### 3.1.3 Complete ineffability

In this subsection we provide a characterisation of the *completely ineffable* cardinals<sup>6</sup> in terms of the  $\alpha$ -Ramseys. To arrive at such a characterisation, we need a slight strengthening of the  $<\omega$ -Ramsey cardinals, namely the *coherent  $<\omega$ -Ramseys* as defined in 3.16. Note that a coherent  $<\omega$ -Ramsey is precisely a cardinal satisfying the  $\omega$ -filter property, as defined in [Holy and Schlicht, 2018].

The following theorem shows that assuming coherency does yield a strictly stronger large cardinal notion. The idea of its proof is closely related to the proof of Theorem 3.23 (the indescribability of normal  $n$ -Ramseys), but the main difference is that we want everything to occur locally inside our weak  $\kappa$ -models. We will need another lemma from [Abramson et al., 1977]:

<sup>6</sup>See Section 1.3 for a definition of the completely ineffable cardinals.

**LEMMA 3.28** ([Abramson et al., 1977]). *Let  $\kappa$  be inaccessible,  $X \subseteq \kappa$  and  $\varphi$  a  $\Sigma_1^1$ -formula such that  $(V_\kappa, \in, X) \models \varphi[X]$ . Then*

$$\{\alpha < \kappa \mid (V_\alpha, \in, X \cap V_\alpha) \models \varphi[X \cap V_\alpha]\}$$

*is a club.* ■

**THEOREM 3.29** (N.). *Every coherent  $<\omega$ -Ramsey is a stationary limit of  $<\omega$ -Ramseys.*

**PROOF.** Let  $\kappa$  be coherent  $<\omega$ -Ramsey. Let  $\theta \gg \kappa$  be regular and let  $\mathcal{M}_0 \prec H_\theta$  be a weak  $\kappa$ -model with  $V_\kappa \subseteq \mathcal{M}_0$ . Let then player I play arbitrarily while player II plays according to their coherent winning strategies in  $\mathcal{G}_n(\kappa)$ , yielding a weak  $\kappa$ -model  $\mathcal{M} \prec H_\theta$  with an  $\mathcal{M}$ -normal  $\mathcal{M}$ -measure  $\mu := \bigcup_{n < \omega} \mu_n$  on  $\kappa$ .

Assume towards a contradiction that

$$X := \{\xi < \kappa \mid \xi \text{ is } <\omega\text{-Ramsey}\} \notin \mu.$$

Since  $X = \bigcap \vec{X}$  and  $\vec{X} \in \mathcal{M}$ , where  $X_n := \{\xi < \kappa \mid \xi \text{ is } n\text{-Ramsey}\}$ , we must have by  $\mathcal{M}$ -normality of  $\mu$  that there is a smallest  $k < \omega$  such that  $\neg X_k \in \mu$ . Note that  $\neg X_k \in \mathcal{M}_0$  by elementarity, so that  $\neg X_k \in \mu_0$  as well. Perform the  $k + 1$  steps as in the proof of Theorem 3.23 with  $\varphi(\xi)$  being ‘ $\xi$  is  $k$ -Ramsey’<sup>7</sup>, so that we get a weak  $\kappa$ -model  $\mathcal{M}_{k+1} \prec H_\theta$ , an  $\mathcal{M}_{k+1}$ -normal  $\mathcal{M}_{k+1}$ -measure  $\tilde{\mu}_{k+1}$  on  $\kappa$ , a  $\Sigma_1$ -formula  $\varphi(v, v_1, v_2, \dots, v_{2k+1})$  and sequences  $\langle \mathcal{A}^{(0)}, \dots, \mathcal{A}^{(k)} \rangle$  and  $\langle B^{(0)}, \dots, B^{(k-1)} \rangle$  such that

$$V_{\kappa+1} \models \varphi[\kappa, \mathcal{A}^{(0)}, B^{(0)}, \mathcal{A}^{(1)}, B^{(1)}, \dots, \mathcal{A}^{(k-1)}, B^{(k-1)}, \mathcal{A}^{(k)}] \quad (2)$$

and there is a  $Y \in \tilde{\mu}_{k+1}$  with  $Y \subseteq \neg X_k$  such that given any  $\xi \in Y$ ,

$$V_{\xi+1} \models \neg \varphi[\xi, \mathcal{A}_\xi^{(0)}, B^{(0)} \cap V_\xi, \mathcal{A}_\xi^{(1)}, B^{(1)} \cap V_\xi, \dots, \mathcal{A}_\xi^{(k-1)}, B^{(k-1)} \cap V_\xi, \mathcal{A}_\xi^{(k)}], \quad (3)$$

where  $\mathcal{A}^{(i)} = [\vec{A}^{(i)}]_{\mu_i} \in \text{Ult}(\mathcal{M}_i, \mu_i)$  as in the proof of Theorem 3.21.

Since  $\kappa$  in particular is  $\Sigma_1^1$ -indescribable, Lemma 3.28 implies that we get a club  $C \subseteq \kappa$  of reflection points of (2). Let  $\mathcal{M}_{k+2} \supseteq \mathcal{M}_{k+1}$  be a weak  $\kappa$ -model

with  $\mathcal{A}^{(k)} \in \mathcal{M}_{k+2}$ , where the above  $(n+1)$ -steps ensured that the  $B^{(i)}$ 's and the remaining  $\mathcal{A}^{(i)}$ 's are all elements of  $\mathcal{M}_{k+1}$ . In particular, as  $C$  is a definable subset in the  $\mathcal{A}^{(i)}$ 's and  $B^{(i)}$ 's we also get that  $C \in \mathcal{M}_{k+2}$ . Letting  $\tilde{\mu}_{k+2}$  be the associated measure on  $\kappa$ ,  $\mathcal{M}_{k+2}$ -normality of  $\tilde{\mu}_{k+2}$  ensures that  $C \in \tilde{\mu}_{k+2}$ . Now define, for every  $\alpha < \kappa$ ,

$$S_\alpha := \{\xi \in Y \mid \forall i \leq k : \mathcal{A}^{(i)} \cap V_\alpha = A_\xi^{(i)} \cap V_\alpha\}$$

and note that  $S_\alpha \in \tilde{\mu}_{k+2}$  for every  $\alpha < \kappa$ . Write  $\vec{S} := \langle S_\alpha \mid \alpha < \kappa \rangle$  and note that since  $\vec{S}$  is definable it is an element of  $\mathcal{M}_{k+2}$  as well. Then  $\mathcal{M}_{k+2}$ -normality of  $\tilde{\mu}_{k+2}$  ensures that  $\Delta \vec{S} \in \tilde{\mu}_{k+2}$ , so that  $C \cap \Delta \vec{S} \in \tilde{\mu}_{k+2}$  as well. But letting  $\zeta \in C \cap \Delta \vec{S}$  we see, as in the proof of Theorem 3.21, that

$$V_{\zeta+1} \models \varphi[\zeta, A_\zeta^{(0)}, B^{(0)} \cap V_\zeta, A_\zeta^{(1)}, B^{(1)} \cap V_\zeta, \dots, A_\zeta^{(k)}]$$

since  $\Delta \vec{S} \subseteq Y$ , contradicting (3). Hence  $X \in \mu$ , and since  $\mathcal{M} \prec H_\theta$  we have that  $\mathcal{M}$  is correct about stationary subsets of  $\kappa$ , meaning that  $\kappa$  is a stationary limit of  $<\omega$ -Ramseys. ■

Now, having established the strength of this large cardinal notion, we move towards complete ineffability. We then arrive at the following characterisation, influenced by the proof of Theorem 1.3.4 in [Abramson et al., 1977]:

**THEOREM 3.30 (N).** *A cardinal  $\kappa$  is completely ineffable if and only if it is coherent  $<\omega$ -Ramsey.*

**PROOF.** ( $\Leftarrow$ ): Assume  $\kappa$  is a coherent  $<\omega$ -Ramsey cardinal, witnessed by strategies  $\langle \tau_n \mid n < \omega \rangle$ . Let  $f : [\kappa]^2 \rightarrow 2$  be arbitrary and form the sequence  $\langle A_\alpha^f \mid \alpha < \kappa \rangle$  as

$$A_\alpha^f := \{\beta > \alpha \mid f(\{\alpha, \beta\}) = 0\}.$$

Let  $\mathcal{M}_f$  be a transitive weak  $\kappa$ -model with  $\vec{A}^f \in \mathcal{M}_f$ , and let  $\mu_f$  be the associated  $\mathcal{M}_f$ -measure on  $\kappa$  given by  $\tau_0$ .<sup>7</sup> 1-Ramseyness of  $\kappa$  ensures that  $\mu_f$  is normal, meaning  $\triangle \mu_f$  is stationary in  $\kappa$ . Define a new sequence  $\vec{B}^f$  as the  $\mu_f$ -positive part of  $\vec{A}^f$ .<sup>8</sup> Then  $B_\alpha^f \in \mu_f$  for all  $\alpha < \kappa$ , so that normality of  $\mu_f$  implies that  $\triangle \vec{B}^f$  is stationary.

Let now  $\mathcal{M}'_f$  be a transitive weak  $\kappa$ -model with  $\mathcal{M}_f \subseteq \mathcal{M}'_f$  and  $\mu_f \in \mathcal{M}'_f$ , and use  $\tau_1$  to get an  $\mathcal{M}'_f$ -measure  $\mu'_f \supseteq \mu_f$  on  $\kappa$ . Then  $\triangle \vec{B}^f \cap \{\xi < \kappa \mid A_\xi^f \in \mu_f\}$  and  $\triangle \vec{B}^f \cap \{\xi < \kappa \mid A_\xi^f \notin \mu_f\}$  are both elements of  $\mathcal{M}'_f$ , so one of them is in  $\mu'_f$ ; set  $H_f$  to be that one. Note that  $H_f$  is now both stationary in  $\kappa$  and homogeneous for  $f$ .

Now let  $g : [H_f]^2 \rightarrow 2$  be arbitrary and again form

$$A_\alpha^g := \{\beta \in H_f \mid \beta > \alpha \wedge g(\{\alpha, \beta\}) = 0\}$$

for  $\alpha \in H_f$ . Let  $\mathcal{M}_{f,g} \supseteq \mathcal{M}'_f$  be a transitive weak  $\kappa$ -model with  $\vec{A}^g \in \mathcal{M}_{f,g}$  and use  $\tau_2$  to get an  $\mathcal{M}_{f,g}$ -measure  $\mu_{f,g} \supseteq \mu'_f$  on  $\kappa$ . As before we then get a stationary  $H_{f,g} \in \mu'_{f,g}$  which is homogeneous for  $g$ . We can continue in this fashion since  $\tau_n \subseteq \tau_{n+1}$  for all  $n < \omega$ . Define then

$$R := \{A \subseteq \kappa \mid \exists \vec{f} : H_{\vec{f}} \subseteq A\},$$

where the  $\vec{f}$ 's range over finite sequences of functions as above; i.e.  $f_0 : [\kappa]^2 \rightarrow 2$  and  $f_{k+1} : [H_{f_k}] \rightarrow 2$  for  $k < \omega$ . This is clearly a stationary class which satisfies that whenever  $A \in R$  and  $g : [A]^2 \rightarrow 2$ , we can find  $H \in R$  which is homogeneous for  $f$ . Indeed, if we let  $\vec{f}$  be such that  $H_{\vec{f}} \subseteq A$ , which exists as  $A \in R$ , then we can simply let  $H := H_{\vec{f},g}$ . This shows that  $\kappa$  is completely ineffable.

( $\Rightarrow$ ): Now assume that  $\kappa$  is completely ineffable and let  $R$  be the corresponding stationary class. We show that  $\kappa$  is  $n$ -Ramsey for all  $n < \omega$  by induction, where we inductively make sure that the resulting strategies are coherent as well. Let player I in  $\mathcal{G}_0(\kappa)$  play  $\mathcal{M}_0$  and enumerate  $\mathcal{P}(\kappa) \cap \mathcal{M}_0$  as  $\vec{A}^0 = \langle A_\alpha^0 \mid \alpha < \kappa \rangle$  such that  $A_\xi^0 \subseteq A_\zeta^0$  implies  $\xi \leq \zeta$ . For  $\alpha < \kappa$  define sequences  $r_\alpha : \alpha \rightarrow 2$  as  $r_\alpha(\xi) = 1$  iff

<sup>7</sup>Technically we would have to require that  $\mathcal{M}_f \prec H_\theta$  for some regular  $\theta > \kappa$  to be able to use  $\tau_0$ , but note that we could simply get a measure on  $\text{Hull}^{H_\theta}(\mathcal{M}_f)$  and restrict it to  $\mathcal{M}_f$ . We will use this throughout the proof.

<sup>8</sup>The  $\mu$ -positive part was defined in Claim 3.26.

$\alpha \in A_\xi^0$ . Let  $<_{\text{lex}}^\alpha$  be the lexicographical ordering on  ${}^\alpha 2$ . Define now a colouring  $f : [\kappa]^2 \rightarrow 2$  as

$$f(\{\alpha, \beta\}) := \begin{cases} 0 & \text{if } r_{\min(\alpha, \beta)} <_{\text{lex}}^{\min(\alpha, \beta)} r_{\max(\alpha, \beta)} \upharpoonright \min(\alpha, \beta) \\ 1 & \text{otherwise} \end{cases}$$

Let  $H_0 \in R$  be homogeneous for  $f$ , using that  $\kappa$  is completely ineffable. For  $\alpha < \kappa$  consider now the sequence  $\langle r_\xi \upharpoonright \alpha \mid \xi \in H_0 \wedge \xi > \alpha \rangle$ , which is of length  $\kappa$  so there is an  $\eta \in [\alpha, \kappa)$  satisfying that  $r_\beta \upharpoonright \alpha = r_\gamma \upharpoonright \alpha$  for every  $\beta, \gamma \in H_0$  with  $\eta \leq \beta < \gamma$ . Define  $g : \kappa \rightarrow \kappa$  as  $g(\alpha)$  being the least such  $\eta$ , which is then a continuous non-decreasing cofinal function, making the set of fixed points of  $g$  club in  $\kappa$  – call this club  $C$ .

Since  $H_0$  is stationary we can pick some  $\zeta \in C \cap H_0$ . As  $\zeta \in C$  we get  $g(\zeta) = \zeta$ , meaning that  $r_\beta \upharpoonright \zeta = r_\gamma \upharpoonright \zeta$  holds for every  $\beta, \gamma \in H_0$  with  $\zeta \leq \beta < \gamma$ . As  $\zeta$  is also a member of  $H_0$  we can let  $\beta := \zeta$ , so that  $r_\zeta = r_\gamma \upharpoonright \zeta$  holds for every  $\gamma \in H_0, \gamma > \zeta$ . Now, by definition of  $r_\alpha$  we get that for every  $\alpha, \gamma \in H_0 \cap C$  with  $\alpha \leq \gamma$  and  $\xi < \alpha$ ,  $\alpha \in A_\xi^0$  iff  $\gamma \in A_\xi^0$ . Define thus the  $\mathcal{M}_0$ -measure  $\mu_0$  on  $\kappa$  as

$$\begin{aligned} \mu_0(A_\xi^0) = 1 & \quad \text{iff} \quad (\forall \beta \in H_0 \cap C)(\beta > \xi \rightarrow \beta \in A_\xi^0) \\ & \quad \text{iff} \quad (\exists \beta \in H_0 \cap C)(\beta > \xi \wedge \beta \in A_\xi^0), \end{aligned}$$

where the last equivalence is due to the above-mentioned property of  $H_0 \cap C$ . Note that the choice of enumeration implies that  $\mu_0$  is indeed a filter. Letting

$$\vec{B} := \langle B_\alpha \mid \alpha < \kappa \rangle$$

be the  $\mu_0$ -positive part of  $\vec{A}^0$ , it is also simple to check that  $H_0 \cap C \subseteq \Delta \vec{B}$ , making  $\mu_0$  normal and hence also both  $\mathcal{M}_0$ -normal and good, showing that  $\kappa$  is 0-Ramsey.

Assume now that  $\kappa$  is  $n$ -Ramsey and let  $\langle \mathcal{M}_0, \mu_0, \dots, \mathcal{M}_n, \mu_n, \mathcal{M}_{n+1} \rangle$  be a partial play of  $\mathcal{G}_{n+1}(\kappa)$ . Enumerate  $\mathcal{P}(\kappa) \cap \mathcal{M}_{n+1}$  as  $\vec{A}^{n+1} = \langle A_\xi^{n+1} \mid \xi < \kappa \rangle$ , again satisfying that  $\xi \leq \zeta$  whenever  $A_\xi^{n+1} \subseteq A_\zeta^{n+1}$ , but also such that given any  $\xi < \kappa$  there are  $\zeta, \zeta' \in (\xi, \kappa)$  satisfying that  $A_\zeta^{n+1} \in \mathcal{P}(\kappa) \cap \mathcal{M}_n$  and  $A_{\zeta'}^{n+1} \in (\mathcal{P}(\kappa) \cap \mathcal{M}_{n+1}) - \mathcal{M}_n$ . The plan now is to do the same thing as before, but we also have to check that the resulting measure extends the previous ones.

Let  $H_n \in R$  and  $C$  be club in  $\kappa$  such that  $H_n \cap C \subseteq \Delta\mu_n$ , which exist by our inductive assumption. For  $\alpha < \kappa$  define  $r_\alpha : \alpha \rightarrow 2$  as  $r_\alpha(\xi) = 1$  iff  $\alpha \in A_\xi^{n+1}$ , and define a colouring  $f : [H_n]^2 \rightarrow 2$  as

$$f(\{\alpha, \beta\}) := \begin{cases} 0 & \text{if } r_{\min(\alpha, \beta)} <_{\text{lex}}^{\min(\alpha, \beta)} r_{\max(\alpha, \beta)} \upharpoonright \min(\alpha, \beta) \\ 1 & \text{otherwise} \end{cases}$$

As  $H_n \in R$  there is an  $H_{n+1} \in R$  homogeneous for  $f$ . Just as before, define  $g : \kappa \rightarrow \kappa$  as  $g(\alpha)$  being the least  $\eta \in [\alpha, \kappa)$  such that  $r_\beta \upharpoonright \alpha = r_\gamma \upharpoonright \alpha$  for every  $\beta, \gamma \in H_{n+1}$  with  $\eta \leq \beta < \gamma$ , and let  $D$  be the club of fixed points of  $g$ . As above we get that given any  $\alpha, \gamma \in H_{n+1} \cap D$  with  $\alpha \leq \gamma$  and  $\xi < \alpha$ ,  $\alpha \in A_\xi^{n+1}$  iff  $\gamma \in A_\xi^{n+1}$ . Define then the  $\mathcal{M}_{n+1}$ -measure  $\mu_{n+1}$  on  $\kappa$  as

$$\begin{aligned} \mu_{n+1}(A_\xi^{n+1}) = 1 & \quad \text{iff } (\forall \beta \in H_{n+1} \cap D \cap C)(\beta > \xi \rightarrow \beta \in A_\xi^{n+1}) \\ & \quad \text{iff } (\exists \beta \in H_{n+1} \cap D \cap C)(\beta > \xi \wedge \beta \in A_\xi^{n+1}). \end{aligned}$$

Then  $H_{n+1} \cap D \cap C \subseteq \Delta\mu_{n+1}$ , making  $\mu_{n+1}$  normal,  $\mathcal{M}_{n+1}$ -normal and good, just as before. It remains to show that  $\mu_n \subseteq \mu_{n+1}$ . Let thus  $A \in \mu_n$  be given, and say  $A = A_\xi^{n+1} = A_\eta^n$ , where  $\vec{A}^n$  was the enumeration of  $\mathcal{P}(\kappa) \cap \mathcal{M}_n$  used at the  $n$ 'th stage. Then by definition of  $\mu_n$  we get that for every  $\beta \in H_n \cap C$  with  $\beta > \eta$ ,  $\beta \in A_\eta^n$ . We need to show that

$$(\exists \beta \in H_{n+1} \cap D \cap C)(\beta > \xi \wedge \beta \in A_\xi^{n+1})$$

holds. But here we can simply pick a  $\beta > \max(\xi, \eta)$  with

$$\beta \in H_{n+1} \cap D \cap C \subseteq H_n \cap C.$$

This shows that  $\mu_n \subseteq \mu_{n+1}$ , making  $\kappa$   $(n+1)$ -Ramsey and thus inductively also coherent  $<\omega$ -Ramsey. ■

### 3.2 THE COUNTABLE CASE

This section covers the (strategic)  $\gamma$ -Ramsey cardinals whenever  $\gamma$  has countable cofinality. This case is special because it is in contrast with the uncountable cofinal-

ity case, as we cannot ensure that the final measure in  $\mathcal{G}_\gamma^\theta(\kappa)$  is countably complete and so the existence of winning strategies might depend on  $\theta$ .

### 3.2.1 [Strategic] $\omega$ -Ramsey cardinals

We now move to the strategic  $\omega$ -Ramsey cardinals and their relationship to the virtual cardinals that we introduced in Chapter 2.

**THEOREM 3.31** (Schindler-N.). *Let  $\kappa < \theta$  be regular cardinals. Then  $\kappa$  is faintly  $\theta$ -measurable iff player II has a winning strategy in  $\mathcal{C}_\omega^\theta(\kappa)$ .*

PROOF. ( $\Leftarrow$ ): Fix a winning strategy  $\sigma$  for player II in  $\mathcal{C}_\omega^\theta(\kappa)$ . Let  $g \subseteq \text{Col}(\omega, H_\theta^V)$  be  $V$ -generic and in  $V[g]$  fix an elementary chain  $\langle \mathcal{M}_n \mid n < \omega \rangle$  of weak  $\kappa$ -models  $\mathcal{M}_n \prec H_\theta^V$  in  $V$  such that  $H_\theta^V \subseteq \bigcup_{n < \omega} \mathcal{M}_n$ , using that  $\theta$  is regular in  $V$  and has countable cofinality in  $V[g]$ . Player II follows  $\sigma$ , resulting in a  $H_\theta^V$ -normal  $H_\theta^V$ -measure  $\mu$  on  $\kappa$ .

We claim that  $\text{Ult}(H_\theta^V, \mu)$  is well-founded, so assume not, witnessed by a sequence  $\langle g_n \mid n < \omega \rangle$  of functions  $g_n: \kappa \rightarrow \theta$  such that  $g_n \in H_\theta^V$  and

$$\{\alpha < \kappa \mid g_{n+1}(\alpha) < g_n(\alpha)\} \in \mu.$$

Now, in  $V$ , define a tree  $\mathcal{T}$  of triples  $(f, M_f, \mu_f)$  such that  $f: \kappa \rightarrow \theta$ ,  $M_f$  is a weak  $\kappa$ -model,  $\mu_f$  is an  $M_f$ -measure on  $\kappa$  and letting  $f_0 <_{\mathcal{T}} \dots <_{\mathcal{T}} f_n = f$  be the  $\mathcal{T}$ -predecessors of  $f$ ,

- $\langle M_{f_0}, \mu_{f_0}, \dots, M_{f_n}, \mu_{f_n} \rangle$  is a partial play of  $\mathcal{C}_\omega^\theta(\kappa)$  in which player II follows  $\sigma$ ; and
- $\{\alpha < \kappa \mid f_{k+1}(\alpha) < f_k(\alpha)\} \in \mu_{f_{k+1}}$  for every  $k < n$ .

Now the  $g_n$ 's induce a cofinal branch through  $\mathcal{T}$  in  $V[g]$ , so by absoluteness of well-foundedness there is a cofinal branch  $b$  through  $\mathcal{T}$  in  $V$  as well. But  $b$  now gives us a play of  $\mathcal{C}_\omega^\theta(\kappa)$  where player II is following  $\sigma$  but player I wins, a contradiction. Thus  $\text{Ult}(H_\theta^V, \mu)$  is well-founded, so that the ultrapower embedding

$$\pi: H_\theta^V \rightarrow \text{Ult}(H_\theta^V, \mu)$$

witnesses that  $\kappa$  is faintly  $\theta$ -measurable.

( $\Rightarrow$ ) : Assume that  $\kappa$  is faintly  $\theta$ -measurable. Let  $\mathbb{P}$  be a forcing  $\dot{\mu}$  a  $\mathbb{P}$ -name for an  $H_\theta^V$ -normal  $H_\theta^V$ -measure on  $\kappa$  and  $\dot{\pi}$  a  $\mathbb{P}$ -name for the associated ultrapower embedding. Define a strategy for player II in  $\mathcal{C}_\omega^\theta(\kappa)$  as follows: Whenever player I plays  $\mathcal{M}_n$  then fix some  $\mathbb{P}$ -condition  $p_n$  such that, letting  $\langle f_i^n \mid i < k \rangle$  enumerate all functions in  $\mathcal{M}_n$  with domain  $\kappa$ ,

$$p_n \Vdash \check{\mu} \cap \mathcal{M}_n = \check{\mu}_n \cap \forall i < \check{k} : \dot{\pi}(\check{f}_i^n)(\check{\kappa}) = \check{\alpha}_i^{n\top},$$

with  $\mu_n, \alpha_i^n \in V$ . Note here that we can ensure  $\mu_n \in V$  because it is finite. Also, ensure that the  $p_n$ 's are  $\leq$ -decreasing. Assume now that  $\text{Ult}(\mathcal{M}_\omega, \mu_\omega)$  is ill-founded, witnessed by functions  $g_n \in {}^\kappa \mathcal{M}_\omega \cap \mathcal{M}_\omega$  for  $n < \omega$ . Then  $g_n = f_{i_n}^{k_n}$  for some  $k_n, i_n < \omega$ , and hence  $p_{k_{n+1}} \Vdash \check{\alpha}_{i_{n+1}}^{k_{n+1}} < \check{\alpha}_{i_n}^{k_n\top}$  for every  $n < \omega$ , so in  $V$  we get an  $\omega$ -sequence of strictly decreasing ordinals,  $\nexists$ . ■

We note that the above Theorem along with our results from Chapter 2 show that winning the Cohen games does not guarantee weak compactness.

**COROLLARY 3.32 (N).** *Let  $\kappa$  be inaccessible.*

- (i) *The existence of a winning strategy for player II in  $\mathcal{C}_\omega^\theta(\kappa)$  for all regular  $\theta > \kappa$  does not imply that  $\kappa$  is weakly compact;*
- (ii) *If player II wins  $\mathcal{C}_\kappa(\kappa)$  then  $\kappa$  is weakly compact.*

**PROOF.** The first claim is directly by Proposition 2.48 and Theorem 3.31, and the second claim is because the hypothesis implies that player II wins  $\mathcal{G}_0(\kappa)$  so that inaccessibility of  $\kappa$  makes  $\kappa$  weakly compact – see e.g. [Gitman, 2011] for this characterisation of weak compactness. ■

Here is a near-analogous result of Theorem 3.31 for the  $\mathcal{G}_\omega^\theta(\kappa)$  game.

**THEOREM 3.33 (Schindler-N).** *Let  $\kappa < \theta$  be regular cardinals. If  $\kappa$  is virtually  $\theta$ -prestrong then player II has a winning strategy in  $\mathcal{G}_\omega^\theta(\kappa)$ , and if player II has a winning strategy in  $\mathcal{G}_\omega^\theta(\kappa)$  then  $\kappa$  is faintly  $\theta$ -power-measurable. In particular,  $\mathcal{G}_\omega^\theta(\kappa)^L \sim \mathcal{C}_\omega^\theta(\kappa)^L$ .*

PROOF. The second statement is exactly like the ( $\Leftarrow$ ) direction in the previous theorem, so we show the first statement. Assume  $\kappa$  is virtually  $\theta$ -prestrong and fix a regular  $\theta > \kappa$ , a transitive  $\mathcal{M} \in V$ , a poset  $\mathbb{P}$  and, in  $V^{\mathbb{P}}$ , an elementary embedding  $\pi: H_\theta^V \rightarrow \mathcal{M}$  with  $\text{crit } \pi = \kappa$ . Fix a name  $\dot{\mu}$  and a  $\mathbb{P}$ -condition  $p$  such that

$$p \Vdash^\Gamma \dot{\mu} \text{ is a weakly amenable } \check{H}_\theta\text{-normal good } \check{H}_\theta\text{-measure}^\top.$$

We now define a strategy  $\sigma$  for player II in  $\mathcal{G}_\omega^\theta(\kappa)$  as follows. Whenever player I plays a weak  $\kappa$ -model  $\mathcal{M}_n \prec H_\theta^V$ , player II fixes  $p_n \in \mathbb{P}$ , an  $\mathcal{M}_n$ -measure  $\mu_n$  and a function  $\pi_n: \mathcal{M}_n \rightarrow \pi(\mathcal{M}_n)$  such that  $p_0 \leq p$ ,  $p_n \leq p_k$  for every  $k \leq n$  and that

$$p_n \Vdash^\Gamma \dot{\mu} \cap \check{\mathcal{M}}_n = \check{\mu}_n \cap \check{\mu}_n = \dot{\mu} \restriction \check{\mathcal{M}}_n^\top. \quad (1)$$

Note that by the Ancient Kunen Lemma 1.4 we get that  $\pi \restriction \mathcal{M}_n \in \mathcal{M} \subseteq V$ , so such  $\pi_n$  always exist in  $V$ . The  $\mu_n$ 's also always exist in  $V$ , by weak amenability of  $\mu$ . Player II responds to  $\mathcal{M}_n$  with  $\mu_n$ . It is clear that the  $\mu_n$ 's are legal moves for player II, so it remains to show that  $\mu_\omega := \bigcup_{n < \omega} \mu_n$  has a well-founded ultrapower. Assume it has not, so that we have a sequence  $\langle g_n \mid n < \omega \rangle$  consisting of functions  $g_n: \kappa \rightarrow \mathcal{M}_\omega := \bigcup_{n < \omega} \mathcal{M}_n$  such that  $g_n \in \mathcal{M}_\omega$  and

$$X_{n+1} := \{\alpha < \kappa \mid g_{n+1}(\alpha) < g_n(\alpha)\} \in \mu_\omega \quad (2)$$

for every  $n < \omega$ . Without loss of generality we can assume that  $g_n, X_n \in \mathcal{M}_n$ . Then (2) implies that  $p_{n+1} \Vdash^\Gamma \dot{\pi}(\check{g}_{n+1})(\check{\kappa}) < \dot{\pi}(\check{g}_n)(\check{\kappa})^\top$ , but by (1) this also means that

$$p_{n+1} \Vdash^\Gamma \check{\pi}_{n+1}(\check{g}_{n+1})(\check{\kappa}) < \check{\pi}_n(\check{g}_n)(\check{\kappa})^\top,$$

so defining, in  $V$ , the ordinals  $\alpha_n := \pi_n(g_n)(\kappa)$ , (3) implies that  $\alpha_{n+1} < \alpha_n$  for all  $n < \omega$ ,  $\frac{1}{2}$ . So  $\mu_\omega$  has a well-founded ultrapower, making  $\sigma$  a winning strategy. ■

We get the following immediate corollary:

**COROLLARY 3.34** (N.-Schindler). *Strategic  $\omega$ -Ramseys are downwards absolute to  $L$ , and the existence of a strategic  $\omega$ -Ramsey cardinal is equiconsistent with the existence of a virtually measurable cardinal. Further, in  $L$  the two notions are equivalent.* ■

Note also that the proof of Theorem 3.33 shows that whenever  $\kappa$  is strategic  $\omega$ -Ramsey then for every regular  $\nu > \kappa$  there is a generic extension in which there exists a weakly amenable  $H_\nu^V$ -normal  $H_\nu$ -measure on  $\kappa$ .

We end this section with a result showing precisely where in the large cardinal hierarchy the strategic  $\omega$ -Ramsey cardinals and  $\omega$ -Ramsey cardinals lie, namely that strategic  $\omega$ -Ramseys are equiconsistent with *remarkables* and  $\omega$ -Ramseys are strictly below. Theorem 4.8 of [Gitman and Welch, 2011] showed that 2-iterables are limits of remarkables, and our Propositions 3.12 and 3.40 show that  $\omega$ -Ramseys are limits of 1-iterables, so that the strategic  $\omega$ -Ramseys and the  $\omega$ -Ramseys both lie strictly between the 2-iterables and 1-iterables. [Holy and Schlicht, 2018] showed that  $\omega$ -Ramseys are consistent with  $V = L$ .

Remarkable cardinals were introduced in [Schindler, 2000b], and they were shown to be equivalent to virtually supercompacts in [Gitman and Schindler, 2018], and thus by Theorem 2.4 also equivalent to virtually strong cardinals. To maintain consistent terminology we will therefore denote remarkables by simply virtually strong/supercompacts.

Combining Corollaries 3.34 and 2.12 we get the following immediate corollary:

**COROLLARY 3.35** (N.-Schindler). *Strategic  $\omega$ -Ramsey cardinals are equiconsistent with virtually strong cardinals.* ■

Now, using these results we show that the strategic  $\omega$ -Ramseys have strictly stronger consistency strength than the  $\omega$ -Ramseys.

**THEOREM 3.36** (N.). *Virtually supercompact cardinals are strategic  $\omega$ -Ramsey limits of  $\omega$ -Ramsey cardinals.*

**PROOF.** Let  $\kappa$  be virtually supercompact. We can then find a transitive  $M$  closed under  $2^\kappa$ -sequences and a generic elementary embedding  $\pi : H_\nu^V \rightarrow M$  for some

$\nu > 2^\kappa$ . We will show that  $\kappa$  is  $\omega$ -Ramsey in  $M$ . Note that remarkables are clearly virtually measurable, and thus by Theorem 3.33 also strategic  $\omega$ -Ramsey; let  $\tau_\theta$  be the winning strategy for player II in  $\mathcal{G}_\omega^\theta(\kappa)$  for all regular  $\theta > \kappa$ .

In  $M$  we fix some regular  $\theta > \kappa$  and let  $\sigma$  be some strategy for player I in  $\mathcal{G}_\omega^\theta(\kappa)^M$ . Since  $M$  is closed under  $2^\kappa$ -sequences it means that  $\mathcal{P}(\mathcal{P}(\kappa)) \subseteq M$  and thus that  $M$  contains all possible filters on  $\kappa$ . We let player II follow  $\tau$ , which produces a play  $\sigma * \tau$  in which player II wins. But all player II's moves are in  $\mathcal{P}(\mathcal{P}(\kappa))$  and hence in  $M$ , and as  $M$  is furthermore closed under  $\omega$ -sequences,  $\sigma * \tau \in M$ . This means that  $M$  sees that  $\sigma$  is not winning, so  $\kappa$  is  $\omega$ -Ramsey in  $M$ .

This also implies that  $\kappa$  is a limit of  $\omega$ -Ramseys in  $H_\nu$ . But as  $\kappa$  is virtually supercompact it holds that  $H_\kappa \prec_2 V$ , in analogy with the same property for strong and supercompacts, and as being  $\omega$ -Ramsey is a  $\Pi_2$ -notion this means that  $\kappa$  is a limit of  $\omega$ -Ramseys. ■

This immediately yields the following corollary:

**COROLLARY 3.37** (N.-Schindler). *If  $\kappa$  is a strategic  $\omega$ -Ramsey cardinal then*

$$L_\kappa \models \ulcorner \text{there is a proper class of } \omega\text{-Ramseys} \urcorner. \quad \dashv$$

### 3.2.2 $(\omega, \alpha)$ -Ramsey cardinals

A natural generalisation of the  $\gamma$ -Ramsey definition is to require more iterability of the last measure. Of course, by Proposition 3.12 we have that  $\mathcal{G}_\gamma(\kappa, \zeta)$  is equivalent to  $\mathcal{G}_\gamma(\kappa)$  when  $\text{cof } \gamma > \omega$  so the next definition is only interesting whenever  $\text{cof } \gamma = \omega$ .

**DEFINITION 3.38** (N.). Let  $\alpha, \beta$  be ordinals. Then a cardinal  $\kappa$  is  $(\alpha, \beta)$ -**Ramsey** if player I does not have a winning strategy in  $\mathcal{G}_\alpha^\theta(\kappa, \beta)$  for all regular  $\theta > \kappa$ .<sup>9</sup> ○

**DEFINITION 3.39** ([Gitman, 2011]). A cardinal  $\kappa$  is  $\alpha$ -**iterable** if for every subset  $A \subseteq \kappa$  there exists a *transitive* weak  $\kappa$ -model  $\mathcal{M}$  with  $A \in \mathcal{M}$  and an  $\alpha$ -good  $\mathcal{M}$ -measure  $\mu$  on  $\mathcal{M}$ . ○

---

<sup>9</sup>Note that an  $\alpha$ -Ramsey cardinal is the same as an  $(\alpha, 0)$ -Ramsey cardinal.

**PROPOSITION 3.40 (N).** *If  $\beta > 0$  then every  $(\alpha, \beta)$ -Ramsey is a  $\beta$ -iterable stationary limit of  $\beta$ -iterables.*

**PROOF.** Fix  $\beta > 0$ , an ordinal  $\alpha$  and an  $(\alpha, \beta)$ -Ramsey cardinal  $\kappa$ . Fix a subset  $A \subseteq \kappa$  and let  $\mathcal{M}_0 := \text{cHull}^{H_{\kappa^+}}(\{A, \kappa\} \cup \kappa)$ . Now let player I play  $\mathcal{M}_0$  and play arbitrary *transitive* legal moves for the rest of the  $\mathcal{G}_\alpha^\theta(\kappa, \beta)$  game. Since  $\kappa$  is  $(\alpha, \beta)$ -Ramsey this strategy is not winning for player I, meaning that there exists a play  $\vec{\mu}$  by player II such that player II wins against the strategy.

Let  $\mathcal{M}$  be the final model of this game, and  $\mu$  the final measure. By definition  $\mu$  is now a  $\beta$ -good  $\mathcal{M}$ -measure on  $\kappa$ . Since  $\mathcal{M}$  is transitive by choice of our strategy for player I, this shows that  $\kappa$  is  $\beta$ -iterable.

That  $\kappa$  is  $\beta$ -iterable is reflected to some  $H_\theta$ , so let now  $(\mathcal{N}, \in, \nu)$  be a result of a play of  $\mathcal{G}_\alpha^\theta(\kappa, \beta)$  in which player II won. Then  $\mathcal{N} \prec H_\theta$ , so that  $\kappa$  is also  $\beta$ -iterable in  $\mathcal{N}$ . Since being  $\beta$ -iterable is witnessed by a subset of  $\kappa$  and  $\beta > 0$  implies<sup>10</sup> that we get a  $\kappa$ -powerset preserving  $j : \mathcal{N} \rightarrow \mathcal{P}$ ,  $\mathcal{P}$  also thinks that  $\kappa$  is  $\beta$ -iterable, making  $\kappa$  a stationary limit of  $\beta$ -iterables by elementarity. ■

We now move towards Theorem 3.44 which gives an upper consistency bound for the  $(\omega, \alpha)$ -Ramseys. We first recall a few definitions and a folklore lemma.

**DEFINITION 3.41.** For an infinite ordinal  $\alpha$ , a cardinal  $\kappa$  is  $\alpha$ -**Erdős** for  $\alpha \leq \kappa$  if given any club  $C \subseteq \kappa$  and regressive  $c : [C]^{<\omega} \rightarrow \kappa$  there is a set  $H \in [C]^\alpha$  homogeneous for  $c$ ; i.e. that  $|c''[H]^n| \leq 1$  holds for every  $n < \omega$ . ◦

**DEFINITION 3.42.** A set of indiscernibles  $I$  for a structure  $\mathcal{M} = (M, \in, A)$  is **remarkable** if  $I - \iota$  is a set of indiscernibles for  $(M, \in, A, \langle \xi \mid \xi < \iota \rangle)$  for every  $\iota \in I$ .<sup>11</sup> ◦

**LEMMA 3.43 (Folklore).** *Let  $\kappa$  be  $\alpha$ -Erdős where  $\alpha \in [\omega, \kappa]$  and let  $C \subseteq \kappa$  be club. Then any structure  $\mathcal{M}$  in a countable language  $\mathcal{L}$  with  $\kappa + 1 \subseteq \mathcal{M}$  has a remarkable set of indiscernibles  $I \in [C]^\alpha$ .*

<sup>10</sup>Recall that  $\beta$ -good for  $\beta > 0$  in particular implies weak amenability.

<sup>11</sup>Note that this terminology is not at all related to remarkable *cardinals*.

PROOF. Let  $\langle \varphi_n \mid n < \omega \rangle$  enumerate all  $\mathcal{L}$ -formulas and define  $c : [C]^{<\omega} \rightarrow \kappa$  as follows. For an increasing sequence  $\alpha_1 < \dots < \alpha_{2n} \in C$  let

$$\begin{aligned} c(\{\alpha_1, \dots, \alpha_{2n}\}) &:= \text{the least } \lambda < \alpha_1 \text{ such that} \\ &\exists \delta_1 < \dots < \delta_k \exists m < \omega : \lambda = \langle m, \delta_1, \dots, \delta_k \rangle \wedge \\ &\mathcal{M} \not\models \varphi_m[\vec{\delta}, \alpha_1, \dots, \alpha_n] \leftrightarrow \varphi_m[\vec{\delta}, \alpha_{n+1}, \dots, \alpha_{2n}] \end{aligned}$$

if such a  $\lambda$  exists, and  $c(s) = 0$  otherwise. Clearly  $c$  is regressive, so since  $\kappa$  is  $\alpha$ -Erdős we get a homogeneous  $I \in [C]^\alpha$  for  $c$ ; i.e. that  $|c[I]^n| \leq 1$  for every  $n < \omega$ . Then  $c(\{\alpha_1, \dots, \alpha_{2n}\}) = 0$  for every  $\alpha_1, \dots, \alpha_{2n} \in I$ , as otherwise there exists an  $m < \omega$  and  $\delta_1 < \dots < \delta_k$  such that for any  $\alpha_1 < \dots < \alpha_{2n} \in I$ ,

$$\mathcal{M} \not\models \varphi_m[\vec{\delta}, \alpha_1, \dots, \alpha_n] \leftrightarrow \varphi_m[\vec{\delta}, \alpha_{n+1}, \dots, \alpha_{2n}]. \quad (\dagger)$$

But then simply pick  $\alpha_1 < \dots < \alpha_{2n} < \alpha'_1 < \dots < \alpha'_{2n}$  so that both  $\{\alpha_1, \dots, \alpha_{2n}\}$  and  $\{\alpha'_1, \dots, \alpha'_{2n}\}$  witnesses  $(\dagger)$ ; then either  $\{\alpha_1, \dots, \alpha_n, \alpha'_1, \alpha'_n\}$  or  $\{\alpha_1, \dots, \alpha_n, \alpha'_{n+1}, \dots, \alpha'_{2n}\}$  also witnesses that  $(\dagger)$  fails,  $\not\vdash$ . ■

**THEOREM 3.44 (N.).** *Let  $\alpha \in [\omega, \omega_1]$  be additively closed. Then any  $\alpha$ -Erdős cardinal is a limit of  $(\omega, \alpha)$ -Ramsey cardinals.*

PROOF. Let  $\kappa$  be  $\alpha$ -Erdős,  $\theta > \kappa$  a regular cardinal and  $\beta < \kappa$  any ordinal. Use the above Lemma 3.43 to get a set of remarkable indiscernibles  $I \in [\kappa]^\alpha$  for the structure  $(H_\theta, \in, \langle \xi \mid \xi < \beta \rangle)$ , and let  $\iota \in I$  be the least indiscernible in  $I$ . We will show that player I has no winning strategy in  $\mathcal{G}_\omega^\theta(\iota, \alpha)$ , so by the proof of Theorem 5.5(d) in [Holy and Schlicht, 2018] it suffices to find a weak  $\iota$ -model  $\mathcal{M} \prec H_\theta$  and an  $\alpha$ -good  $\mathcal{M}$ -measure on  $\iota$ . Define

$$\mathcal{M} := \text{Hull}^{H_\theta}(\iota \cup I) \prec H_\theta$$

and let  $\pi : I \rightarrow I$  be the right-shift map. Since  $I$  is remarkable,  $I (= I - \iota)$  is a set of indiscernibles for the structure  $(H_\theta, \in, \langle \xi \mid \xi < \iota \rangle)$ , so that  $\pi$  induces an

elementary embedding  $j : \mathcal{M} \rightarrow \mathcal{M}$  with  $\text{crit } j = \iota$ , given as

$$j(\tau^{\mathcal{M}}[\vec{\xi}, \iota_{i_0}, \dots, \iota_{i_k}]) := \tau^{\mathcal{M}}[\vec{\xi}, \iota_{i_0+1}, \dots, \iota_{i_k+1}],$$

with  $\vec{\xi} \subseteq \iota$ . Since  $j$  is trivially  $\iota$ -powerset preserving we get that  $\mathcal{M} \prec H_\theta$  is a weak  $\iota$ -model satisfying  $\text{ZFC}^-$  with a 1-good  $\mathcal{M}$ -measure  $\mu_j$  on  $\iota$ . Furthermore, as we can linearly iterate  $\mathcal{M}$  simply by applying  $j$  we get an  $\alpha$ -iteration of  $\mathcal{M}$  since there are  $\alpha$ -many indiscernibles. Note that at limit stages  $\gamma < \alpha$  our iteration sends  $\tau^{\mathcal{M}}[\vec{\xi}, \iota_{i_0}, \dots, \iota_{i_k}]$  to  $\tau^{\mathcal{M}}[\vec{\xi}, \iota_{i_0+\gamma}, \dots, \iota_{i_k+\gamma}]$  so here we are using that  $\alpha$  is additively closed.

This shows that player I has no winning strategy in  $\mathcal{G}_\omega^\theta(\iota, \alpha)$ . Since  $\iota > \beta$  and  $\beta < \kappa$  was arbitrary,  $\kappa$  is a limit of  $\eta$  such that player I has no winning strategy in  $\mathcal{G}_\omega^\theta(\eta, \alpha)$ . If we repeat this procedure for all regular  $\theta > \kappa$  we get by the pigeonhole principle that  $\kappa$  is a limit of  $(\omega, \alpha)$ -Ramsey cardinals. ■

As Theorem 4.5 in [Gitman and Schindler, 2018] shows that  $(\alpha+1)$ -iterable cardinals have  $\alpha$ -Erdős cardinals below them for  $\alpha \geq \omega$  additively closed, this shows that the  $(\omega, \alpha)$ -Ramseys form a strict hierarchy. Further, as  $\alpha$ -Erdős cardinals are consistent with  $V = L$  when  $\alpha < \omega_1^L$  and  $\omega_1$ -iterable cardinals are not consistent with  $V = L$ , we also get that  $(\omega, \alpha)$ -Ramsey cardinals are consistent with  $V = L$  if  $\alpha < \omega_1^L$  and that they are not if  $\alpha = \omega_1$ .

### 3.2.3 [Strategic] $(\omega+1)$ -Ramsey cardinals

The next step is then to consider  $(\omega+1)$ -Ramseys, which turn out to cause a considerable jump in consistency strength. We first need the following result which is implicit in [Mitchell, 1979] and in the proof of Lemma 1.3 in [Donder et al., 1981] – see also [Dodd, 1982] and [Gitman, 2011].

**THEOREM 3.45** (Jensen-Mitchell). *A cardinal  $\kappa$  is Ramsey if and only if every  $A \subseteq \kappa$  is an element of a weak  $\kappa$ -model  $\mathcal{M}$  such that there exists a weakly amenable countably complete  $\mathcal{M}$ -measure on  $\kappa$ .* ■

The following theorem then supplies us with a lower bound for the strength of the  $(\omega+1)$ -Ramsey cardinals. It should be noted that a better lower bound will

be shown in Theorem 3.58, but we include this Ramsey lower bound as well for completeness.

**THEOREM 3.46 (N.).** *Every  $(\omega+1)$ -Ramsey cardinal is a Ramsey limit of Ramseys.*

PROOF. Let  $\kappa$  be  $(\omega+1)$ -Ramsey and  $A \subseteq \kappa$ . Let  $\sigma$  be a strategy for player I in  $\mathcal{G}_{\omega+1}^{\kappa^+}(\kappa)$  satisfying that whenever  $\vec{\mathcal{M}}_\alpha * \vec{\mu}_\alpha$  is consistent with  $\sigma$  it holds that  $A \in \mathcal{M}_0$  and  $\mu_\alpha \in \mathcal{M}_{\alpha+1}$  for all  $\alpha \leq \omega$ . Then  $\sigma$  is not winning as  $\kappa$  is  $(\omega+1)$ -Ramsey, so we may fix a play  $\sigma * \vec{\mu}_\alpha$  of  $\mathcal{G}_{\omega+1}^{\kappa^+}(\kappa)$  in which player II wins. Then by the choice of  $\sigma$  we get that  $\mu_\omega$  is a weakly amenable  $\mathcal{M}_\omega$ -measure on  $\kappa$ , and by the rules of  $\mathcal{G}_{\omega+1}^{\kappa^+}(\kappa)$  it is also countably complete (it is even normal), which makes  $\kappa$  Ramsey by the above Theorem 3.45.

Since  $\kappa$  is Ramsey,  $\mathcal{M}_\omega \models \ulcorner \kappa \text{ is Ramsey} \urcorner$  as well. Letting  $j : \mathcal{M}_\omega \rightarrow \mathcal{N}$  be the  $\kappa$ -powerset preserving embedding induced by  $\mu_\omega$ ,  $\kappa$ -powerset preservation implies that  $\mathcal{N} \models \ulcorner \kappa \text{ is Ramsey} \urcorner$ . This then implies that  $\kappa$  is a stationary limit of Ramsey cardinals inside  $\mathcal{M}_\omega$ , and thus also in  $V$  by elementarity. ■

As for the *consistency* strength of the strategic  $(\omega+1)$ -Ramsey cardinals, we get the following result that they reach a measurable cardinal. The proof of the following is closely related to the proof due to Silver and Solovay that player II having a winning strategy in the *cut and choose game* is equiconsistent with a measurable cardinal – see e.g. p. 249 in [Kanamori and Magidor, 1978].

**THEOREM 3.47 (N.).** *If  $\kappa$  is a strategic  $(\omega+1)$ -Ramsey cardinal then, in  $V^{\text{Col}(\omega, 2^\kappa)}$ , there is a transitive class  $N$  and an elementary embedding  $j : V \rightarrow N$  with  $\text{crit } j = \kappa$ . In particular, the existence of a strategic  $(\omega+1)$ -Ramsey cardinal is equiconsistent with the existence of a measurable cardinal.*

PROOF. Set  $\mathbb{P} := \text{Col}(\omega, 2^\kappa)$  and let  $\sigma$  be player II's winning strategy in  $\mathcal{G}_{\omega+1}^{\kappa^+}(\kappa)$ . Let  $\dot{\mathcal{M}}$  be a  $\mathbb{P}$ -name of an  $\omega$ -sequence  $\langle \mathcal{M}_n \mid n < \omega \rangle$  of weak  $\kappa$ -models  $\mathcal{M}_n \in V$  such that  $\mathcal{M}_n \prec H_{\kappa^+}^V$  and  $\mathcal{P}(\kappa)^V \subseteq \bigcup_{n < \omega} \mathcal{M}_n$ , and let  $\dot{\mu}$  be a  $\mathbb{P}$ -name for the  $\omega$ -sequence of  $\sigma$ -responses to the  $\mathcal{M}_n$ 's in  $\mathcal{G}_{\omega+1}^{\kappa^+}(\kappa)^V$ .

Assume that there is a  $\mathbb{P}$ -condition  $p$  which forces ill-foundedness of the generic ultrapower  $\text{Ult}(V, \bigcup_n \dot{\mu}_n)$ , meaning that we can fix a  $\mathbb{P}$ -name  $\dot{f}$  for an  $\omega$ -sequence

$\langle f_n \mid n < \omega \rangle$  such that

$$p \Vdash \dot{X}_n := \{\alpha < \kappa \mid \dot{f}_{n+1}(\alpha) < \dot{f}_n(\alpha)\} \in \bigcup_{n < \omega} \dot{\mu}_n.$$

Now, in  $V$ , we fix some large regular  $\theta \gg \kappa$  and a countable  $\mathcal{N} \prec H_\theta$  such that  $\dot{\mathcal{M}}, \dot{\mu}, \dot{f}, H_{\kappa^+}^V, \sigma, p \in \mathcal{N}$ . We can find an  $\mathcal{N}$ -generic  $g \subseteq \mathbb{P}^{\mathcal{N}}$  in  $V$  with  $p \in g$  since  $\mathcal{N}$  is countable, so that  $\mathcal{N}[g] \in V$ . But the play  $\dot{\mathcal{M}}_n^g * \dot{\mu}_n^g$  is a play of  $\mathcal{G}_\omega^{\kappa^+}(\kappa)^V$  which is according to  $\sigma$ , meaning that  $\bigcup_{n < \omega} \dot{\mu}_n^g$  is normal and in particular countably complete (in  $V$ ). Then  $\bigcap_{n < \omega} \dot{X}_n^g \neq \emptyset$ , but if  $\alpha \in \bigcap_{n < \omega} \dot{X}_n^g$  then  $\langle \dot{f}_n^g(\alpha) \mid n < \omega \rangle$  is a strictly decreasing  $\omega$ -sequence of ordinals,  $\nless$ . This means that  $\text{Ult}(V, \bigcup_n \mu_n)$  is indeed well-founded.

This conclusion is well-known to imply that  $\kappa$  is a measurable in an inner model; see e.g. Lemma 4.2 in [Kellner and Shelah, 2011].  $\blacksquare$

The above Theorem 3.47 then answers Question 9.2 in [Holy and Schlicht, 2018] in the negative, asking if  $\lambda$ -Ramseys are strategic  $\lambda$ -Ramseys for uncountable cardinals  $\lambda$ , as well as answering Question 9.7 from the same paper in the positive, asking whether strategic fully Ramseys are equiconsistent with a measurable.

### 3.3 THE GENERAL CASE

#### 3.3.1 Gitman's cardinals

In this subsection we define the strongly and super Ramsey cardinals which were introduced in [Gitman, 2011] and investigate further connections between these and the  $\alpha$ -Ramsey cardinals. First, a definition.

**DEFINITION 3.48** ([Gitman, 2011]). A cardinal  $\kappa$  is **strongly Ramsey** if every  $A \subseteq \kappa$  is an element of a transitive  $\kappa$ -model  $\mathcal{M}$  with a weakly amenable  $\mathcal{M}$ -normal  $\mathcal{M}$ -measure  $\mu$  on  $\kappa$ . Furthermore, if  $\mathcal{M} \prec H_{\kappa^+}$  then we say that  $\kappa$  is **super Ramsey**.  
 $\circ$

Note that since the model  $\mathcal{M}$  in question is a  $\kappa$ -model it is closed under countable sequences, so that the measure  $\mu$  is automatically countably complete. The definition of the strongly Ramseys is thus exactly the same as the characterisation of Ramsey cardinals, with the added condition that the model is closed under  $<\kappa$ -

sequences. [Gitman, 2011] shows that every super Ramsey cardinal is a strongly Ramsey limit of strongly Ramsey cardinals, and that  $\kappa$  is strongly Ramsey iff every  $A \subseteq \kappa$  is an element of a transitive  $\kappa$ -model  $\mathcal{M} \models \text{ZFC}$  with a weakly amenable  $\mathcal{M}$ -normal  $\mathcal{M}$ -measure  $\mu$  on  $\kappa$ .

Now, a first connection between the  $\alpha$ -Ramseys and the strongly and super Ramseys is the result in [Holy and Schlicht, 2018] that fully Ramsey cardinals are super Ramsey limits of super Ramseys. The following result then shows that the strongly and super Ramseys are sandwiched between the almost fully Ramseys and the fully Ramseys:

**THEOREM 3.49** (N.-Welch). *Every strongly Ramsey cardinal is a stationary limit of almost fully Ramseys.*

**PROOF.** Let  $\kappa$  be strongly Ramsey and let  $\mathcal{M} \models \text{ZFC}$  be a transitive  $\kappa$ -model with  $V_\kappa \in \mathcal{M}$  and  $\mu$  a weakly amenable  $\mathcal{M}$ -normal  $\mathcal{M}$ -measure. Let  $\gamma < \kappa$  have uncountable cofinality and  $\sigma \in \mathcal{M}$  a strategy for player I in  $\mathcal{G}_\gamma(\kappa)^\mathcal{M}$ . Now, whenever player I plays  $\mathcal{M}_\alpha \in \mathcal{M}$  let player II play  $\mu \cap \mathcal{M}_\alpha$ , which is an element of  $\mathcal{M}$  by weak amenability of  $\mu$ . As  $\mathcal{M}^{<\kappa} \subseteq \mathcal{M}$  the resulting play is inside  $\mathcal{M}$ , so  $\mathcal{M}$  sees that  $\sigma$  is not winning.

Now, letting  $j_\mu : \mathcal{M} \rightarrow \mathcal{N}$  be the induced embedding,  $\kappa$ -powerset preservation of  $j_\mu$  implies that  $\mu$  is also a weakly amenable  $\mathcal{N}$ -normal  $\mathcal{N}$ -measure on  $\kappa$ . This means that we can copy the above argument to ensure that  $\kappa$  is also almost fully Ramsey in  $\mathcal{N}$ , entailing that it is a stationary limit of almost fully Ramseys in  $\mathcal{M}$ . But note now that  $\lambda$  is almost fully Ramsey iff it is almost fully Ramsey in a transitive ZFC-model containing  $H_{(2^\lambda)^+}$  as an element by Theorem 5.5(e) in [Holy and Schlicht, 2018], so that  $\kappa$  being inaccessible,  $V_\kappa \in \mathcal{M}$  and  $\mathcal{M}$  being transitive implies that  $\kappa$  really is a stationary limit of almost fully Ramseys. ■

### 3.3.2 Downwards absoluteness to $K$

Lastly, we consider the question of whether the  $\alpha$ -Ramseys are downwards absolute to  $K$ , which turns out to at least be true in many cases. The below Theorem 3.51 then also answers Question 9.4 from [Holy and Schlicht, 2018] in the positive, asking

whether  $\alpha$ -Ramseys are downwards absolute to the Dodd-Jensen core model for  $\alpha \in [\omega, \kappa]$  a cardinal. We first recall the definition of  $0^\sharp$ .

**DEFINITION 3.50.**  $0^\sharp$  is “the sharp for a strong cardinal”, meaning the minimal sound active mouse  $\mathcal{M}$  with  $\mathcal{M} \restriction \text{crit}(\dot{F}^{\mathcal{M}}) \models \ulcorner \text{There exists a strong cardinal} \urcorner$ , with  $\dot{F}^{\mathcal{M}}$  being the top extender of  $\mathcal{M}$ .  $\circ$

**THEOREM 3.51** (N.-Welch). *Assume  $0^\sharp$  does not exist. Let  $\lambda$  be a limit ordinal with uncountable cofinality and let  $\kappa$  be  $\lambda$ -Ramsey. Then*

$$K \models \ulcorner \kappa \text{ is a } \lambda\text{-Ramsey cardinal} \urcorner.$$

**PROOF.** Note first that  $\kappa^{+K} = \kappa^+$  by [Schindler, 1997], since  $\kappa$  in particular is weakly compact. Let  $\sigma \in K$  be a strategy for player I in  $\mathcal{G}_\lambda^{\kappa^+}(\kappa)^K$ , so that a play following  $\sigma$  will produce weak  $\kappa$ -models  $\mathcal{M} \prec K \restriction \kappa^+$ . We can then define a strategy  $\tilde{\sigma}$  for player I in  $\mathcal{G}_\lambda^{\kappa^+}(\kappa)$  as follows. Firstly let

$$\tilde{\sigma}(\emptyset) := \text{Hull}^{H_{\kappa^+}}(K \restriction \kappa \cup \sigma(\emptyset)).$$

Assuming now that  $\langle \tilde{\mathcal{M}}_\alpha, \tilde{\mu}_\alpha \mid \alpha < \gamma \rangle$  is a partial play of  $\mathcal{G}_\lambda^{\kappa^+}(\kappa)$  which is consistent with  $\tilde{\sigma}$ , we have two cases. If  $\tilde{\mu}_\alpha \in K$  for every  $\alpha < \gamma$  then let  $\langle \mathcal{M}_\alpha \mid \alpha < \gamma \rangle$  be the corresponding models played in  $\mathcal{G}_\lambda^{\kappa^+}(\kappa)^K$  from which the  $\tilde{\mathcal{M}}_\alpha$ ’s are derived and let

$$\tilde{\sigma}(\langle \tilde{\mathcal{M}}_\alpha, \tilde{\mu}_\alpha \mid \alpha < \gamma \rangle) := \text{Hull}^{H_{\kappa^+}}(K \restriction \kappa \cup \sigma(\langle \mathcal{M}_\alpha, \tilde{\mu}_\alpha \mid \alpha < \gamma \rangle)),$$

and otherwise let  $\tilde{\sigma}$  play arbitrarily. As  $\kappa$  is  $\lambda$ -Ramsey (in  $V$ ) there exists a play  $\langle \tilde{\mathcal{M}}_\alpha, \tilde{\mu}_\alpha \mid \alpha \leq \lambda \rangle$  of  $\mathcal{G}_\lambda^{\kappa^+}(\kappa)$  which is consistent with  $\tilde{\sigma}$  in which player II won. Note that  $\tilde{\mathcal{M}}_\lambda \cap K \restriction \kappa^+ \prec K \restriction \kappa^+$  so let  $\mathcal{N}$  be the transitive collapse of  $\tilde{\mathcal{M}}_\lambda \cap K \restriction \kappa^+$ . But if  $j : \mathcal{N} \rightarrow K \restriction \kappa^+$  is the uncollapse then  $\text{crit } j$  is both an  $\mathcal{N}$ -cardinal and also  $> \kappa$  because we ensured that  $K \restriction \kappa \subseteq \mathcal{N}$ . This means that  $j = \text{id}$  because  $\kappa$  is the largest  $\mathcal{N}$ -cardinal by elementarity in  $K \restriction \kappa^+$ , so that  $\tilde{\mathcal{M}}_\lambda \cap K \restriction \kappa^+ = \mathcal{N}$  is a transitive elementary substructure of  $K \restriction \kappa^+$ , making it an initial segment of  $K$ .

Now, since  $\mu := \tilde{\mu}_\lambda$  is a countably complete weakly amenable  $K|o(\mathcal{N})$ -measure<sup>12</sup>, Theorem 1.49 shows that  $\mu \in K^{13}$ , so that we can then define a strategy  $\tau$  for player II in  $\mathcal{G}_\lambda^{\kappa^+}(\kappa)^K$  as simply playing  $\mu \cap \mathcal{N} \in K$  whenever player I plays  $\mathcal{N}$ . Since  $\mu = \tilde{\mu}_\lambda$  we also have that  $\mu \cap \mathcal{M}_\alpha = \tilde{\mu}_\alpha \cap \mathcal{M}_\alpha$ , so that  $\sigma$  will eventually play  $\mathcal{N}$ , making  $\tau$  win against  $\sigma$ .<sup>14</sup> ■

Note that the only thing we used  $\text{cof } \lambda > \omega$  for in the above proof was to ensure that  $\mu$  was countably complete. If now  $\kappa$  instead was either genuine or normal  $\alpha$ -Ramsey for any limit ordinal  $\alpha$  then  $\mu_\alpha$  would also be countably complete and weakly amenable, so the same proof shows the following:

**COROLLARY 3.52** (N.-Welch). *Assume  $0^\sharp$  does not exist and let  $\alpha$  be any limit ordinal. Then every genuine and every normal  $\alpha$ -Ramsey cardinal is downwards absolute to  $K$ . In particular, if  $\alpha$  is a limit of limit ordinals then every  $<\alpha$ -Ramsey cardinal is downwards absolute to  $K$  as well.* ■

### 3.3.3 Indiscernible games

We now move to the strategic versions of the  $\alpha$ -Ramsey hierarchy. The first thing we want to do is define  $\alpha$ -very Ramsey cardinals from [Sharpe and Welch, 2011], and show the tight connection between these and the strategic  $\alpha$ -Ramseys. We need a few more definitions. Recall the definition of a remarkable set of indiscernibles from Definition 3.42.

**DEFINITION 3.53.** A **good set of indiscernibles** for a structure  $\mathcal{M}$  is a set  $I \subseteq \mathcal{M}$  of remarkable indiscernibles for  $\mathcal{M}$  such that  $\mathcal{M} \restriction \iota \prec \mathcal{M}$  for any  $\iota \in I$ . ○

A key result of [Sharpe and Welch, 2011] involves a translation procedure between indiscernibles and measures. The following result is translating from a measure to indiscernibles and is a special case of [Sharpe and Welch, 2011, Lemma 2.9]:

<sup>12</sup>Here we use that  $\mathcal{N} \triangleleft K$ .

<sup>13</sup>This is where we are using that we are below  $0^\sharp$ .

<sup>14</sup>Note that  $\tau$  is not necessarily a winning strategy – all we know is that it is winning against this particular strategy  $\sigma$ .

**THEOREM 3.54** (Sharpe-Welch). *Let  $\kappa$  be an uncountable cardinal,  $\alpha > \kappa$ , and fix  $A \subseteq \alpha$  and  $a \subseteq \kappa$ . Let  $\mathcal{M} := \langle J_\alpha[A], \in, A \rangle$  and  $m := \langle J_\kappa[a], \in, a \rangle$ . Assume the following:*

- (i)  $m \in \mathcal{M}$ ;
- (ii)  $\mathcal{M}$  and  $m$  are both amenable structures;
- (iii)  $\mathcal{M}$  is a weak  $\kappa$ -model with  $\kappa$  being its largest cardinal;
- (iv) There exists a countably complete weakly amenable  $\mathcal{M}$ -measure  $\mu$  on  $\kappa$ .

*Then there exists a good set of indiscernibles  $I \in \mu$  for  $m$ .* ■

The converse translation procedure, going from a good set of indiscernibles to a measure, is then the following, being part of Lemma 2.18 in [Sharpe and Welch, 2011]:

**THEOREM 3.55** (Sharpe-Welch). *Let  $\kappa$  be an uncountable cardinal,  $a \subseteq \kappa$  and define  $m := \langle J_\kappa[a], \in, a \rangle$ . Assume that*

- (i)  $m$  is amenable;
- (ii)  $m \models \text{ZFC}$ ;
- (iii) There exists a good set of indiscernibles  $I \in [\kappa]^\kappa$  for  $m$ .

*Then there exists an ordinal  $\alpha > \kappa$  and  $A \subseteq \alpha$  such that  $\mathcal{M} := \langle J_\alpha[A], \in, A \rangle$  is an amenable weak  $\kappa$ -model with  $\kappa$  being its largest cardinal,  $m \in \mathcal{M}$  and there exists a countably complete weakly amenable  $\mathcal{M}$ -measure  $\mu$  on  $\kappa$ .* ■

**DEFINITION 3.56** (Sharpe-Welch). Define the **indiscernible game**  $G_\gamma^I(\kappa)$  in  $\gamma$  many rounds as follows<sup>15</sup>

$$\begin{array}{ccccccc} \text{I} & \mathcal{M}_0 & & \mathcal{M}_1 & & \mathcal{M}_2 & \dots \\ \text{II} & & I_0 & & I_1 & & I_2 & \dots \end{array}$$

Here  $\mathcal{M}_\alpha$  is an amenable structure of the form  $(J_\kappa[A], \in, A)$  for some  $A \subseteq \kappa$ ,  $I_\alpha \in [\kappa]^\kappa$  is a good set of indiscernibles for  $\mathcal{M}_\alpha$  and the  $I_\alpha$ 's are  $\subseteq$ -decreasing. Player II wins iff they can continue playing through all the rounds. ○

**DEFINITION 3.57** (Sharpe-Welch). A cardinal  $\kappa$  is  **$\gamma$ -very Ramsey** if player II has a winning strategy in the game  $G_\gamma^I(\kappa)$ . ○

<sup>15</sup>This game is denoted by  $G_r(\kappa, \gamma)$  in [Sharpe and Welch, 2011].

The next couple of results concern the connection between the strategic  $\alpha$ -Ramseys and the  $\alpha$ -very Ramseys. We start with the following:

**THEOREM 3.58 (N.).** *Every  $(\omega+1)$ -Ramsey is an  $\omega$ -very Ramsey stationary limit of  $\omega$ -very Ramseys.*

**PROOF.** Let  $\kappa$  be  $(\omega+1)$ -Ramsey. We will describe a winning strategy for player II in the indiscernible game  $G_\omega^I(\kappa)$ . If player I plays  $\mathcal{M}_0 = (J_\kappa[A_0], \in, A_0)$  in  $G_\omega^I(\kappa)$  then let player I in  $\mathcal{G}_{\omega+1}^{\kappa^+}(\kappa)$  play

$$\mathcal{H}_0 := \text{Hull}^{H_{\kappa^+}}(J_\kappa[A_0] \cup \{\mathcal{M}_0, \kappa, A_0\}) \prec H_{\kappa^+}.$$

Let player I now follow a strategy in  $\mathcal{G}_{\omega+1}^{\kappa^+}(\kappa)$  which starts off with  $\mathcal{H}_0$  and ensures that, whenever  $\vec{\mathcal{M}}_\alpha * \vec{\mu}_\alpha$  is consistent with player I's strategy, then  $\mu_\alpha \in \mathcal{M}_{\alpha+1}$  for all  $\alpha \leq \omega$ . Since player II is not losing in  $\mathcal{G}_{\omega+1}^{\kappa^+}(\kappa)$  there is a play  $\vec{\mathcal{M}}_\alpha * \vec{\mu}_\alpha$  in which player I follows this strategy just described and where player II wins – write  $\mathcal{H}_0^{(\alpha)} := \mathcal{M}_\alpha$  and  $\mu_0^{(\alpha)} := \mu_\alpha$  for the models and measures in this play.

$$\begin{array}{ccccccc} \text{I} & \mathcal{H}_0^{(0)} & \dots & \mathcal{H}_0^{(\omega)} & \mathcal{H}_0^{(\omega+1)} & & \\ \text{II} & & \mu_0^{(0)} & \dots & \mu_0^{(\omega)} & \mu_0^{(\omega+1)} & \end{array}$$

By the choice of player I's strategy we get that  $\mu_0^{(\omega)}$  is both weakly amenable, and it is also countably complete by the rules of  $\mathcal{G}_{\omega+1}^{\kappa^+}(\kappa)$  (it is even normal). Now Theorem 3.54 gives us a set of good indiscernibles  $I_0 \in \mu_0^{(\omega)}$  for  $\mathcal{M}_0$ , as  $\mathcal{M}_0 \in \mathcal{H}_0^{(\omega)}$  and  $\mu_0^{(\omega)}$  is a countably complete weakly amenable  $\mathcal{H}_0^{(\omega)}$ -normal  $\mathcal{H}_0^{(\omega)}$ -measure on  $\kappa$ . Let player II play  $I_0$  in  $G_\omega^I(\kappa)$ . Let now  $\mathcal{M}_1 = (J_\kappa[A_1], \in, A_1)$  be the next play by player I in  $G_\omega^I(\kappa)$ .

$$\begin{array}{ccc} \text{I} & \mathcal{M}_0 & \mathcal{M}_1 \\ \text{II} & & I_0 \end{array}$$

Since  $\mu_0^{(\omega)} = \bigcup_n \mu_0^{(n)}$  we must have that  $I_0 \in \mu_0^{(n_0)}$  for some  $n_0 < \omega$ . In the  $(n_0+1)$ 'st round of  $\mathcal{G}_{\omega+1}^{\kappa^+}(\kappa)$  we change player I's strategy and let player I play

$$\mathcal{H}_1 := \text{Hull}^{H_{\kappa^+}}(J_\kappa[A_0] \cup \{\mathcal{M}_0, \mathcal{M}_1, \kappa, A_0, A_1, \langle \mathcal{H}_0^{(k)}, \mu_0^{(k)} \mid k \leq n_0 \rangle\}) \prec H_{\kappa^+}$$

and otherwise continue following some strategy, as long as the measures played by player II keep being elements of the following models. Our play of the game  $\mathcal{G}_{\omega+1}^{\kappa^+}(\kappa)$  thus looks like the following so far:

$$\begin{array}{ccccccc} \text{I} & \mathcal{H}_0^{(0)} & & \cdots & & \mathcal{H}_0^{(n_0)} & & \mathcal{H}_1 \\ \text{II} & & \mu_0^{(0)} & & \cdots & & \mu_0^{(n_0)} & \end{array}$$

Now player II in  $\mathcal{G}_{\omega+1}^{\kappa^+}(\kappa)$  is not losing at round  $n_0$ , so there is a play extending the above in which player I follows their revised strategy and in which player II wins. As before we get a set  $I'_1 \in \mu_1^{(n_1)}$  of good indiscernibles for  $\mathcal{M}_1$ , where  $n_1 < \omega$ . Since  $I_0 \in \mu_0^{(n_0)} \subseteq \mu_1^{(n_1)}$  we can let player II in  $G_\omega^I(\kappa)$  play  $I_1 := I_0 \cap I'_1 \in \mu_1^{(n_1)}$ . Continuing like this, player II can keep playing throughout all  $\omega$  rounds of  $G_\omega^I(\kappa)$ , making  $\kappa$   $\omega$ -very Ramsey.

As for showing that  $\kappa$  is a stationary limit of  $\omega$ -very Ramseys, let  $\mathcal{M} \prec H_{\kappa^+}$  be a weak  $\kappa$ -model with a weakly amenable countably complete  $\mathcal{M}$ -normal  $\mathcal{M}$ -measure  $\mu$  on  $\kappa$ , which exists by Theorem 3.46 as  $\kappa$  is  $(\omega+1)$ -Ramsey. Then by elementarity  $\mathcal{M} \models \ulcorner \kappa \text{ is } \omega\text{-very Ramsey} \urcorner$  and since  $\kappa$  being  $\omega$ -very Ramsey is absolute between structures having the same subsets of  $\kappa$  it also holds in the  $\mu$ -ultrapower, meaning that  $\kappa$  is a stationary limit of  $\omega$ -very Ramseys by elementarity. ■

The above proof technique can be generalised to the following:

**THEOREM 3.59 (N.).** *For limit ordinals  $\alpha$ , every coherent  $<\omega\alpha$ -Ramsey is  $\omega\alpha$ -very Ramsey.*

**PROOF.** (Sketch) This is basically the same proof as the proof of Theorem 3.58. We do the “going-back” trick in  $\omega$ -chunks, and at limit stages we continue our non-losing strategy in  $\mathcal{G}_{\omega\alpha}^{\kappa^+}(\kappa)$  by using our winning strategy, which we have available as we are assuming coherent  $<\omega\alpha$ -Ramsey. We need  $\alpha$  to be a limit ordinal for this to work, as otherwise we would be in trouble in the last  $\omega$ -chunk, as we cannot just extend the play to get a countably complete measure, which we need to use the proof of Theorem 3.58. ■

As for going from the  $\alpha$ -very Ramseys to the strategic  $\alpha$ -Ramseys we got the following:

**THEOREM 3.60 (N.).** *For  $\gamma$  any ordinal, every coherent  $<\gamma$ -very Ramsey<sup>16</sup> is coherent  $<\gamma$ -Ramsey.<sup>17</sup>*

**PROOF.** The reason why we work with  $<\gamma$ -Ramseys here is to ensure that player II only has to satisfy a closed game condition (i.e. to continue playing throughout all the rounds). If  $\gamma = \beta + 1$  then set  $\zeta := \beta$  and otherwise let  $\zeta := \gamma$ . Let  $\kappa$  be  $\zeta$ -very Ramsey and let  $\tau$  be a winning strategy for player II in  $G_\zeta^I(\kappa)$ . Let  $\mathcal{M}_\alpha \prec H_\theta$  be any move by player I in the  $\alpha$ 'th round of  $\mathcal{G}_\zeta(\kappa)$ . Let  $A_\alpha \subseteq \kappa$  encode all subsets of  $\kappa$  in  $\mathcal{M}_\alpha$  and form now

$$\mathcal{N}_\alpha := (J_\kappa[A_\alpha], \in, A_\alpha),$$

which is a legal move for player I in  $G_\zeta^I(\kappa)$ , yielding a good set of indiscernibles  $I_\alpha \in [\kappa]^\kappa$  for  $\mathcal{N}_\alpha$  such that  $I_\alpha \subseteq I_\beta$  for every  $\beta < \alpha$ . Now by Theorem 3.55 we get a structure  $\mathcal{P}_\alpha$  with  $\mathcal{N}_\alpha \in \mathcal{P}_\alpha$  and a  $\mathcal{P}_\alpha$ -measure  $\tilde{\mu}_\alpha$  on  $\kappa$ , generated by  $I_\alpha$ .<sup>18</sup> Set  $\mu_\alpha := \tilde{\mu}_\alpha \cap \mathcal{M}_\alpha$  and let player II play  $\mu_\alpha$  in  $\mathcal{G}_\zeta(\kappa)$ .

As the  $\mu_\alpha$ 's are generated by the  $I_\alpha$ 's, the  $\mu_\alpha$ 's are  $\subseteq$ -increasing. We have thus created a strategy for player II in  $\mathcal{G}_\zeta(\kappa)$  which does not lose at any round  $\alpha < \gamma$ , making  $\kappa$  coherent  $<\gamma$ -Ramsey. ■

The following result is then a direct corollary of Theorems 3.59 and 3.60:

**COROLLARY 3.61 (N.).** *For limit ordinals  $\alpha$ ,  $\kappa$  is  $\omega\alpha$ -very Ramsey iff it is coherent  $<\omega\alpha$ -Ramsey. In particular,  $\kappa$  is  $\lambda$ -very Ramsey iff it is strategic  $\lambda$ -Ramsey for any  $\lambda$  with uncountable cofinality.* ■

<sup>16</sup>Here the coherency again just means that the winning strategies  $\sigma_\alpha$  for player II in  $G_\alpha^I(\kappa)$  are  $\subseteq$ -increasing.

<sup>17</sup>Here a “coherent  $<\gamma$ -very Ramsey cardinal” is defined from  $\gamma$ -very Ramseys in the same way as coherent  $<\gamma$ -Ramsey cardinals is defined from  $\gamma$ -Ramseys. When  $\gamma$  is a limit ordinal then coherent  $<\gamma$ -very Ramseys are precisely the same as  $\gamma$ -very Ramseys, so this is solely to “subtract one” when  $\gamma$  is a successor ordinal – i.e. a coherent  $<(\gamma + 1)$ -very Ramsey cardinal is the same thing as a  $\gamma$ -very Ramsey cardinal.

<sup>18</sup>By *generated* here we mean that  $X \in \tilde{\mu}_\alpha$  iff  $X$  contains a tail of indiscernibles from  $I_\alpha$ .

We can now use this equivalence to transfer results from the  $\alpha$ -very Ramseys over to the strategic versions. The *completely Ramsey cardinals* are the cardinals topping the hierarchy defined in [Feng, 1990]. A completely Ramsey cardinal implies the consistency of a Ramsey cardinal, see e.g. Theorem 3.51 in [Sharpe and Welch, 2011]. We are going to use the following characterisation of the completely Ramsey cardinals, which is Lemma 3.49 in [Sharpe and Welch, 2011]:

**THEOREM 3.62** (Sharpe-Welch). *A cardinal is completely Ramsey if and only if it is  $\omega$ -very Ramsey.* ■

This, together with Theorem 3.58, immediately yields the following strengthening of Theorem 3.46:

**COROLLARY 3.63** (N.). *Every  $(\omega+1)$ -Ramsey cardinal is a completely Ramsey stationary limit of completely Ramsey cardinals.* ■

The above Theorem 3.60 also yields the following consequence:

**COROLLARY 3.64** (N.). *Every completely Ramsey cardinal is completely ineffable.*

**PROOF.** From Theorem 3.62 we have that being completely Ramsey is equivalent to being  $\omega$ -very Ramsey, so the above Theorem 3.60 then yields that a completely Ramsey cardinal is coherent  $<\omega$ -Ramsey, which we saw in Theorem 3.30 is equivalent to being completely ineffable. ■

Now, moving to the uncountable case, Corollary 3.61 yields that strategic  $\omega_1$ -Ramsey cardinals are  $\omega_1$ -very Ramsey, and Theorem 3.50 in [Sharpe and Welch, 2011] states that  $\omega_1$ -very Ramseys are measurable in the core model  $K$ , assuming  $0^\sharp$  does not exist, which then shows the following theorem. We also include the original direct proof of that theorem, due to Welch.

**THEOREM 3.65** (Welch). *Assuming  $0^\sharp$  does not exist, every strategic  $\omega_1$ -Ramsey cardinal is measurable in  $K$ .*

PROOF. Let  $\kappa$  be strategic  $\omega_1$ -Ramsey, say  $\tau$  is the winning strategy for player II in  $\mathcal{G}_{\omega_1}(\kappa)$ . Jump to  $V[g]$ , where  $g \subseteq \text{Col}(\omega_1, \kappa^+)$  is  $V$ -generic. Since  $\text{Col}(\omega_1, \kappa^+)$  is  $\omega$ -closed,  $V$  and  $V[g]$  have the same countable sequences of  $V$ , so  $\tau$  is still a strategy for player II in  $\mathcal{G}_{\omega_1}(\kappa)^{V[g]}$ , as long as player I only plays elements of  $V$ .

Now let  $\langle \kappa_\alpha \mid \alpha < \omega_1 \rangle$  be an increasing sequence of regular  $K$ -cardinals cofinal in  $\kappa^+$ , let player I in  $\mathcal{G}_{\omega_1}(\kappa)$  play  $\mathcal{M}_\alpha := \text{Hull}^{H_\theta}(K \restriction \kappa_\alpha) \prec H_\theta$  and player II follow  $\tau$ . This results in a countably complete weakly amenable  $K$ -measure  $\mu_{\omega_1}$ , which Theorem 1.49 then shows is actually an element of  $K$ , making  $\kappa$  measurable in  $K$ . ■

A natural question is whether this behaviour persists when going to larger core models. It turns out that the answer is affirmative: every strategic  $\omega_1$ -Ramsey cardinal is also measurable in Steel's core model below a Woodin<sup>19</sup>, a result due to Schindler which we include with his permission here. We will need the following special case of a theorem by Schindler.<sup>20</sup>

**THEOREM 3.66** ([Schindler, 2006a] 3.1). *Assume that there exists no inner model with a Woodin cardinal, let  $\mu$  be a measure on a cardinal  $\kappa$ , and let  $\pi : V \rightarrow \text{Ult}(V, \mu) \cong N$  be the ultrapower embedding. Assume that  $N$  is closed under countable sequences. Write  $K^N$  for the core model constructed inside  $N$ . Then  $K^N$  is a normal iterate of  $K$ , i.e. there is a normal iteration tree  $\mathcal{T}$  on  $K$  of successor length such that  $\mathcal{M}_\infty^\mathcal{T} = K^N$ . Moreover, we have that  $\pi_{0\infty}^\mathcal{T} = \pi \restriction K$ . ■*

**THEOREM 3.67** (Schindler). *Assuming there exists no inner model with a Woodin cardinal, every strategic  $\omega_1$ -Ramsey cardinal is measurable in  $K$ .*

PROOF. Fix a large regular  $\theta \gg 2^\kappa$ . Let  $\kappa$  be strategic  $\omega_1$ -Ramsey and fix a winning strategy  $\sigma$  for player II in  $\mathcal{G}_{\omega_1}(\kappa)$ . Let  $g \subseteq \text{Col}(\omega_1, 2^\kappa)$  be  $V$ -generic and in  $V[g]$  fix an elementary chain  $\langle M_\alpha \mid \alpha < \omega_1 \rangle$  of weak  $\kappa$ -models  $M_\alpha \prec H_\theta^V$  such that  $M_\alpha \in V$ ,  ${}^\omega M_\alpha \subseteq M_{\alpha+1}$  and  $H_{\kappa^+}^V \subseteq M_{\omega_1} := \bigcup_{\alpha < \omega_1} M_\alpha$ .

Note that  $V$  and  $V[g]$  have the same countable sequences since  $\text{Col}(\omega_1, 2^\kappa)$  is  $<\omega_1$ -closed, so we can apply  $\sigma$  to the  $M_\alpha$ 's, resulting in an  $M_{\omega_1}$ -measure  $\mu$  on  $\kappa$ .

<sup>19</sup>See Section 1.4.

<sup>20</sup>That paper assumes the existence of a measurable as well, but by [Jensen and Steel, 2013] we can omit that here.

Let  $j : M_{\omega_1} \rightarrow \text{Ult}(M_{\omega_1}, \mu)$  be the ultrapower embedding. Since we required that  ${}^\omega M_\alpha \subseteq M_{\alpha+1}$  we get that  $\mathcal{M}_{\omega_1}$  is closed under  $\omega$ -sequences in  $V[g]$ , making  $\mu$  countably complete in  $V[g]$ . As we also ensured that  $H_{\kappa^+}^V \subseteq \mathcal{M}_{\omega_1}$  we can lift  $j$  to an ultrapower embedding  $\pi : V \rightarrow \text{Ult}(V, \mu) \cong N$  with  $N$  transitive.

Since  $V$  is closed under  $\omega$ -sequences in  $V[g]$  we get by standard arguments that  $N$  is as well, which means that Theorem 3.66 applies, meaning that

$$\pi \restriction K : K \rightarrow K^N$$

is an iteration map with critical point  $\kappa$ , making  $\kappa$  measurable in  $K$ . ■

## 4 | IDEAL ABSOLUTENESS

Historically, the idea of considering elementary embeddings existing only in generic extensions has been around for a while, but it all started as an analysis of *ideals*. *Precipitous ideals* were introduced in [Galvin et al., 1978] and further analysed in [Jech et al., 1980], being ideals that give rise to well-founded generic ultrapowers.

In this chapter we will introduce the *ideally measurable cardinals*, essentially just switching perspective from the ideals themselves to the cardinals they are on. We then proceed to show how these cardinals relate to “pure” generic cardinals, being proper class versions of the faintly measurable cardinals that we have considered throughout Chapter 2. We start with a definition of the latter.

**DEFINITION 4.1 (GBC).** A cardinal  $\kappa$  is **generically measurable** if there is a generic extension  $V[g]$ , a transitive class  $\mathcal{N} \subseteq V[g]$  and a generic elementary embedding  $\pi: V \rightarrow \mathcal{N}$  with  $\text{crit } \pi = \kappa$ . ◦

Note that, trivially, every generically measurable cardinal is faintly measurable. The corresponding ideal version of this is then the following:

**DEFINITION 4.2.** A cardinal  $\kappa$  is **ideally measurable** if there exists an ideal  $\mathcal{I}$  on  $\mathcal{P}(\theta)$  such that the generic ultrapower  $\text{Ult}(V, \mathcal{I})$  is well-founded in the forcing extension  $V^{\mathbb{P}}$ , where  $\mathbb{P} := \mathcal{P}^V(\kappa)/\mathcal{I}$ . ◦

It should also be noted that [Claverie and Schindler, 2016] generalised the concept of ideally measurables to *ideally strong cardinals* by introducing the concept of *ideal extenders* to capture the strongness properties.

Throughout this chapter we will be interested in how properties of the *forcings* affect the large cardinal structure of a critical point of a generic embedding. We thus define the following:

**DEFINITION 4.3.** Let  $\theta$  be a regular uncountable cardinal,  $\kappa < \theta$  a cardinal and  $\Phi(\kappa)$  a poset property<sup>1</sup>. Then  $\kappa$  is  $\Phi(\kappa)$  **faintly  $\theta$ -measurable** if it is faintly  $\theta$ -measurable, witnessed by a forcing poset satisfying  $\Phi(\kappa)$ . Similarly,  $\kappa$  is  $\Phi(\kappa)$  **generically measurable** if it is generically measurable with the associated forcing satisfying  $\Phi(\kappa)$ .  $\circ$

**DEFINITION 4.4.** A poset property  $\Phi(\kappa)$  is **ideal-absolute** if whenever  $\kappa$  satisfies that there is a  $\Phi(\kappa)$  forcing poset  $\mathbb{P}$  such that, in  $V^{\mathbb{P}}$ , there is a  $V$ -normal  $V$ -measure  $\mu$  on  $\kappa$ , then there is a normal ideal  $\mathcal{I}$  on  $\kappa$  such that  $\mathcal{P}(\kappa)/\mathcal{I}$  is forcing equivalent to a forcing satisfying  $\Phi(\kappa)$ .  $\circ$

Note that this is *almost* saying that  $\Phi(\kappa)$  ideally measurables are equivalent to  $\Phi(\kappa)$  generically measurables, but the only difference is that these definitions require well-foundedness of the target model.

If  $\Phi(\kappa)$  implies  $\omega$ -distributivity then we *do* get well-foundedness for free, however: any witness to the ill-foundedness of the ultrapower is an  $\omega$ -sequence in the generic extension, so  $\omega$ -distributivity implies that this sequence is in  $V$  as well, which is contradicting  $V$ -normality of the measure.

A typical ideal that we will be utilising is the following:

**DEFINITION 4.5.** Let  $\kappa$  be a regular cardinal,  $\mathbb{P}$  a poset and  $\dot{\mu}$  a  $\mathbb{P}$ -name for a  $V$ -normal  $V$ -measure on  $\kappa$ . Then the **induced ideal** is

$$\mathcal{I}(\mathbb{P}, \dot{\mu}) := \{X \subseteq \kappa \mid \|\check{X} \in \dot{\mu}\|_{\mathcal{B}(\mathbb{P})} = 0\},$$

where  $\mathcal{B}(\mathbb{P})$  is the Boolean completion of  $\mathbb{P}$ .  $\circ$

Note that if the generic measure  $\mu$  is  $V$ -normal then  $\mathcal{I}(\mathbb{P}, \dot{\mu})$  is also normal. This ideal will witness our first ideal-absoluteness result, which is a simple rephrasing of a folklore result.

---

<sup>1</sup>Examples of these are having the  $\kappa$ -chain condition, being  $\kappa$ -closed,  $\kappa$ -distributive,  $\kappa$ -Knaster,  $\kappa$ -sized and so on. Formally speaking,  $\Phi(\kappa)$  is a first-order formula  $\varphi(\kappa)$  which is true iff there is a poset  $\mathbb{P}$  such that  $\kappa$  is a cardinal and some first-order formula  $\psi(\kappa, \mathbb{P})$  is true.

**PROPOSITION 4.6** (Folklore). “The  $\kappa^+$ -chain condition” is ideal-absolute.

**PROOF.** Assume  $\mathbb{P}$  has the  $\kappa^+$ -chain condition such that there is a  $\mathbb{P}$ -name  $\dot{\mu}$  for a  $V$ -normal  $V$ -measure on  $\kappa$ . Let  $\mathcal{I} := \mathcal{I}(\mathbb{P}, \dot{\mu})$  – we will show that  $\mathcal{P}(\kappa)/\mathcal{I}$  has the  $\kappa^+$ -chain condition. Assume not and let  $\langle X_\alpha \mid \alpha < \kappa^+ \rangle$  be an antichain of  $\mathcal{P}(\kappa)/\mathcal{I}$ , which by normality of  $\mathcal{I}$  we may assume is pairwise almost disjoint. But this then makes  $\langle \|\check{X}_\alpha \in \dot{\mu}\|_{\mathcal{B}(\mathbb{P})} \mid \alpha < \kappa^+ \rangle$  an antichain of  $\mathbb{P}$  of size  $\kappa^+$ ,  $\nless$ . ■

We next move to distributivity. This property is especially interesting in the context of our generic large cardinals, as an ideal  $\mathcal{I}$  on some cardinal  $\kappa$  is  $\omega$ -distributive precisely if it is precipitous<sup>2</sup>, so that carrying an  $\omega$ -distributive ideal coincides with our definition of *ideally measurable*.

**THEOREM 4.7** (N.). “ $<\lambda$ -distributivity” is ideal-absolute for all regular  $\lambda \in [\omega, \kappa^+]$ .

**PROOF.** Assume that  $\mathbb{P}$  is a  $<\lambda$ -distributive forcing such that there exists a  $\mathbb{P}$ -name  $\dot{\mu}$  for a  $V$ -normal  $V$ -measure on  $\kappa$ . Let  $\mathcal{I} := \mathcal{I}(\mathbb{P}, \dot{\mu})$  – we will show that  $\mathcal{P}(\kappa)/\mathcal{I}$  is  $<\lambda$ -distributive.

Let  $\gamma < \lambda$  and let  $\vec{\mathcal{A}}$  be a  $\gamma$ -sequence of maximum antichains  $\mathcal{A}_\alpha \subseteq \mathcal{P}(\kappa)/\mathcal{I}$  such that  $\mathcal{A}_\beta$  refines  $\mathcal{A}_\alpha$  for  $\alpha \leq \beta$ . We have to show that there is a maximal antichain  $\mathcal{A}$  which refines all the antichains in  $\vec{\mathcal{A}}$ .

Now define for every  $\alpha < \gamma$  the sets

$$\mathcal{A}_\alpha^* := \{ \|\check{X} \in \dot{\mu}\|_{\mathcal{B}(\mathbb{P})} \mid X \in \mathcal{A}_\alpha \}.$$

Note that  $\mathcal{A}_\alpha^*$  is an antichain in  $\mathbb{P}$ . They are also maximal, because if  $p \in \mathbb{P}$  was incompatible with every condition in  $\mathcal{A}_\alpha^*$  then, letting  $X := \Delta\{\kappa - Y \mid Y \in \mathcal{A}_\alpha\}$ , we have that  $p$  is compatible with  $\|\check{X} \in \dot{\mu}\|_{\mathcal{B}(\mathbb{P})}$ , so that  $X \in \mathcal{I}^+$ . But  $X$  is incompatible with everything in  $\mathcal{A}_\alpha$ , contradicting that  $\mathcal{A}_\alpha$  is maximal.

By  $<\lambda$ -distributivity of  $\mathbb{P}$  we get an antichain  $\mathcal{A}^*$  which refines all the antichains in  $\vec{\mathcal{A}}^*$ . But note that for every  $p \in \mathcal{A}^*$ , if we define  $s_p(\alpha)$  to be the unique  $a \in \mathcal{A}_\alpha$  such that  $p \leq a$ , then it holds that  $p \leq \|\Delta s_p \in \dot{\mu}\|_{\mathcal{B}(\mathbb{P})}$ ,<sup>3</sup> so that  $\Delta s_p \in \mathcal{I}^+$ . Now  $\mathcal{A} := \{\Delta s_p \mid p \in \mathcal{A}^*\}$  gives us a maximal antichain which refines all the antichains

---

<sup>2</sup>See [Jech et al., 1980] and [Foreman, 1983].

<sup>3</sup>Here we are using that  $\lambda \leq \kappa^+$  to ensure that the diagonal intersection is in the measure.

in  $\vec{\mathcal{A}}$ . ■

In an unpublished paper, Foreman proved the following:

**THEOREM 4.8** (Foreman). *Let  $\kappa$  be a regular cardinal such that  $2^\kappa = \kappa^+$ , and let  $\lambda \leq \kappa^+$  be an infinite successor cardinal. If player II has a winning strategy in  $\mathcal{G}_\lambda^-(\kappa)$  then  $\kappa$  carries a  $\kappa$ -complete normal precipitous ideal  $\mathcal{I}$  such that  $\mathcal{P}(\kappa)/\mathcal{I}$  has a dense  $<\lambda$ -closed subset of size  $\kappa^+$ .*

Here we improve that result by not relying on the CH-assumption, reaching the conclusion for all regular infinite  $\lambda$ , and also showing  $(\kappa, \kappa)$ -distributivity of the ideal forcing. The argument follows the same overall structure as the original, with more technicalities to achieve the stronger result.

**THEOREM 4.9** (Foreman-N.). *Let  $\kappa$  be a regular cardinal and  $\lambda \leq \kappa^+$  regular infinite. If player II has a winning strategy in  $\mathcal{G}_\lambda^-(\kappa)$  then  $\kappa$  carries a  $\kappa$ -complete normal ideal  $\mathcal{I}$  such that  $\mathcal{P}(\kappa)/\mathcal{I}$  is  $(\kappa, \kappa)$ -distributive and has a dense  $<\lambda$ -closed subset.*

**PROOF.** Set  $\mathbb{P} := \text{Add}(\kappa^+, 1)$  if  $2^\kappa > \kappa^+$  and  $\mathbb{P} := \{\emptyset\}$  otherwise. If  $\kappa$  is measurable then the dual ideal to the measure on  $\kappa$  satisfies all of the wanted properties, so assume that  $\kappa$  is not measurable. Fix a wellordering  $<_{\kappa^+}$  of  $H_{\kappa^+}^V$  and a  $\mathbb{P}$ -name  $\pi$  for a sequence  $\langle \mathcal{N}_\gamma \mid \gamma < \kappa^+ \rangle \in V^{\mathbb{P}}$  such that

- $\mathcal{N}_\gamma \in V$  for every  $\gamma < \kappa^+$ ;
- $\mathcal{N}_{\gamma+1} \prec H_{\kappa^+}^V$  is a  $\kappa$ -model for every  $\gamma < \kappa^+$ ;
- $\mathcal{N}_\delta = \bigcup_{\gamma < \delta} \mathcal{N}_\gamma$  for limit ordinals  $\delta < \kappa^+$ ;
- $\mathcal{N}_\gamma \cup \{\mathcal{N}_\gamma\} \subseteq \mathcal{N}_\beta$  for  $\gamma < \beta < \kappa^+$ ;
- $\mathcal{P}(\kappa)^V \subseteq \bigcup_{\gamma < \kappa^+} \mathcal{N}_\gamma$ .

Define now the auxilliary game  $\mathcal{G}(\kappa)$  of length  $\lambda$  as follows.

I	$\alpha_0$	$\alpha_1$	$\dots$
II	$p_0, \mathcal{M}_0, \mu_0, Y_0$	$p_1, \mathcal{M}_1, \mu_1, Y_1$	$\dots$

Here  $\langle \alpha_\gamma \mid \gamma < \lambda \rangle$  is an increasing continuous sequence of ordinals bounded in  $\kappa^+$ ,  $\vec{p}$  is a decreasing sequence of  $\mathbb{P}$ -conditions satisfying that

$$p_\gamma \Vdash \check{\mathcal{M}}_\gamma = \pi(\check{\alpha}_\gamma) \wedge \check{\mu}_\gamma \text{ is a } \check{\mathcal{M}}_\gamma\text{-normal } \check{\mathcal{M}}_\gamma\text{-measure on } \check{\kappa}^\top$$

such that  $Y_\gamma = \Delta_{\xi < \kappa} X_\xi^{\mu_\gamma}$ , where  $\vec{X}_\xi^{\mu_\gamma} \in H_{\kappa^+}^V$  is the  $<_{\kappa^+}$ -least enumeration of  $\mu_\gamma$ .<sup>4</sup> We require that the  $\mu_\gamma$ 's are  $\subseteq$ -increasing, and player II wins iff she can continue playing throughout all  $\lambda$  rounds. Let  $\mu_\lambda := \bigcup_{\xi < \lambda} \mu_\xi$  be the **final measure** of the play.

To every limit ordinal  $\eta < \kappa^+$  define the **restricted auxilliary game**  $\mathcal{G}(\kappa) \restriction \eta$  in which player I is only allowed to play ordinals  $< \eta$  with the sequence bounded in  $\eta$ . Note that a strategy  $\tau$  for player II is winning in  $\mathcal{G}(\kappa)$  if and only if it is winning in  $\mathcal{G}(\kappa) \restriction \eta$  for all  $\eta < \kappa^+$ , simply because all sequences of ordinals played by player I are bounded in  $\kappa^+$ .

Note that  $\mu_\lambda$  is precisely the tail measure on  $\kappa$  defined by the  $Y_\gamma$ 's; i.e. that  $X \in \mu_\lambda$  iff there exists a  $\delta < \lambda$  such that  $|Y_\delta - X| < \kappa$ . From this it is simple to see that  $\mathcal{G}(\kappa)$  is equivalent to  $\mathcal{G}_\lambda^-(\kappa)$ , so player II has a winning strategy  $\tau_0$  in  $\mathcal{G}(\kappa)$ .

For any winning strategy  $\tau$  in  $\mathcal{G}(\kappa) \restriction \eta$  and to every partial play  $p$  of  $\mathcal{G}(\kappa) \restriction \eta$  consistent with  $\tau$ , define the associated **hopeless ideal**<sup>5</sup>

$$I_p^\tau \restriction \eta := \{X \subseteq \kappa \mid \text{For every play } \vec{\alpha}_\gamma * \tau \text{ extending } p \text{ in } \mathcal{G}(\kappa) \restriction \eta, \\ X \text{ is not in the final measure}\}$$

*Claim 4.10.*  $\mathcal{I} := \bigcap_{\eta < \lambda} I_\emptyset^\tau \restriction \eta$  is normal and  $(\kappa, \kappa)$ -distributive, for every winning strategy  $\tau$  in  $\mathcal{G}(\kappa)$  for player II.

**PROOF OF CLAIM.** For normality, if  $\langle Z_\gamma \mid \gamma < \kappa \rangle$  is a sequence of elements of  $\mathcal{I}$  such that  $Z := \nabla_\gamma Z_\gamma$  is  $\mathcal{I}$ -positive, then there exists a play of  $\mathcal{G}(\kappa) \restriction \eta$  in which player II follows  $\tau$  such that  $Z$  lies in the final measure. If we let player I play sufficiently large ordinals in  $\mathcal{G}(\kappa) \restriction \eta$  we may assume that  $\langle Z_\gamma \mid \gamma < \kappa \rangle$  is a subset and an element of the final model as well, meaning that one of the  $Z_\gamma$ 's also lies in the final measure,  $\nsubseteq$ .

---

<sup>4</sup>We use that  $\mathbb{P}$  is  $\kappa$ -closed to get the  $p_\gamma$ 's as well as to ensure that  $\mathcal{M}_\gamma, \mu_\gamma \in V$ .

<sup>5</sup>This terminology is due to Matt Foreman.

We now show  $(\kappa, \kappa)$ -distributivity. Let  $\mathcal{U} \subseteq \mathcal{P}(\kappa)/\mathcal{I}$  be an unrooted tree of height  $\kappa$  such that every level  $\mathcal{U}_\alpha$  is a maximal antichain of size  $\leq \kappa$ . We have to show that there is a maximal antichain  $\mathcal{A}$  consisting of limit points of branches of  $\mathcal{U}$ . Pick  $X \in \mathcal{U}$  and let  $p$  be a play of  $\mathcal{G}(\kappa) \upharpoonright \eta$  consistent with  $\tau$  with limit model  $\mathcal{M}$  and limit measure  $\mu$ , such that  $X \in \mu$ .

By letting player I in  $p$  play sufficiently large ordinals, we may assume that  $\mathcal{U} \subseteq \mathcal{M}$ , using that  $|\mathcal{U}| \leq \kappa$ , and also that  $b_X := \mathcal{U} \cap \mu \in \mathcal{M}$ . This means that  $d_X := \Delta b_X \in \mathcal{P}(\kappa)/\mathcal{I}$  is a limit point of the branch  $b_X$  through  $\mathcal{U}$ , so that  $\mathcal{A} := \{d_X \mid X \in \mathcal{U}\}$  is a maximal antichain of limit points of branches of  $\mathcal{U}$ , making  $\mathcal{P}(\kappa)/\mathcal{I}$   $(\kappa, \kappa)$ -distributive.  $\dashv$

Fix some limit ordinal  $\eta < \kappa^+$ . We will recursively construct a tree  $\mathcal{T}^\eta$  of height  $\lambda$  which consists of subsets  $X \subseteq \kappa$ , ordered by reverse inclusion. In the following we will talk of player II's moves as subsets of  $\kappa$  – here we are referring to the code of the move. During the construction of the tree we will inductively maintain the following properties of  $\mathcal{T}^\eta \upharpoonright \alpha$  for  $\alpha \leq \lambda$ :

- **TREE STRATEGY:** For every  $\gamma < \alpha$  there is a winning strategy  $\tau_\gamma^\eta$  for player II in  $\mathcal{G}(\kappa) \upharpoonright \eta$  such that for every  $\beta < \gamma$ , the  $\beta$ 'th move by  $\tau_\gamma^\eta$  is an element of  $\mathcal{T}_\beta^\eta$  and  $\tau_\gamma^\eta$  is consistent with  $\tau_\beta^\eta$  for the first  $\beta$ -many rounds.
- **UNIQUE PRE-HISTORY:** Given any  $\beta < \alpha$  and  $Y \in \mathcal{T}_\beta^\eta$  there is a unique partial play  $p$  of  $\mathcal{G}(\kappa) \upharpoonright \eta$  consistent with  $\tau_\beta^\eta$  ending with  $Y$  – we define  $I_Y^\tau := I_p^\tau$  for  $\tau$  being any winning strategy for player II in  $\mathcal{G}(\kappa) \upharpoonright \eta$  satisfying that  $p$  is consistent with  $\tau_\beta^\eta$ .
- **COFINALLY MANY RESPONSES:** Let  $\beta + 1 < \alpha$  and  $Y \in \mathcal{T}_\beta^\eta$ , and set  $p$  to be the unique partial play of  $\mathcal{G}(\kappa) \upharpoonright \eta$  given by the unique pre-history of  $Y$ . Then the  $\mathcal{T}^\eta$ -successors of  $Y$  consists of player II's  $\tau_\beta^\eta$ -responses to  $\tau_\beta^\eta$ -partial plays extending  $p$  such that player I's last move in these partial plays are cofinal in  $\eta$ .<sup>6</sup>
- **POSITIVITY:** If  $\beta < \alpha$  and  $Y \in \mathcal{T}_\beta^\eta$  then  $Y$  is  $I_X^{\tau_\gamma^\eta}$ -positive for every  $\gamma < \beta$  and every  $X \in \mathcal{T}^\eta \upharpoonright \gamma + 1$  with  $X \leq_{\mathcal{T}^\eta} Y$ .<sup>7</sup>

---

<sup>6</sup>The reason why we are dealing with the *restricted* auxilliary games is to achieve this property.

<sup>7</sup>This actually follows from the cofinally many responses, but we include it here for transparency.

- ALMOST DISJOINTNESS PROPERTY: Every level  $\mathcal{T}_\beta^\eta$  consists of pairwise almost disjoint sets.<sup>8</sup>
- HOPELESS IDEAL COHERENCE:  $I_{\langle \rangle}^{\tau_\beta^\eta} \cap \mathcal{P}(Y) = I_Y^{\tau_\beta^\eta} \cap \mathcal{P}(Y)$  for every  $\beta < \alpha$  and  $Y \in \mathcal{T}_\beta^\eta$ .

Note that what we are really aiming for is achieving the hopeless ideal coherence, since that enables us to ensure that if  $X, Y \in \mathcal{T}^\eta$  and  $X \subseteq Y$  then really  $X \geq_{\mathcal{T}^\eta} Y$  – i.e. that we “catch” both  $X$  and  $Y$  in the same play of  $\mathcal{G}(\kappa) \upharpoonright \eta$ . This is crucial to show the  $<\lambda$ -closure of  $\mathcal{T}$ . The rest of the properties are inductive properties we need to ensure this.

Set  $\mathcal{T}_0^\eta := \{\kappa\}$ . Assume that we have built  $\mathcal{T}^\eta \upharpoonright \alpha + 1$  satisfying the inductive assumptions<sup>9</sup> and let  $Y \in \mathcal{T}_\alpha^\eta$  – we need to specify what the  $\mathcal{T}^\eta$ -successors of  $Y$  are. Since  $\kappa$  is weakly compact and not measurable it holds by Proposition 6.4 in [Kanamori, 2008] that  $\text{sat}(I_Y^{\tau_\alpha^\eta}) \geq \kappa^+$ , so we can fix a maximal antichain  $\langle X_\gamma^Y \mid \gamma < \eta \rangle$  of  $I_Y^{\tau_\alpha^\eta}$ -positive sets. By  $\kappa$ -completeness of  $I_Y^{\tau_\alpha^\eta}$  we can by Exercise 22.1 in [Jech, 2006] even ensure that all of the  $X_\gamma^Y$ ’s are pairwise disjoint.

To every  $\gamma < \eta$  we fix a partial play  $p$  of even length of  $\mathcal{G}(\kappa) \upharpoonright \eta$  consistent with  $\tau_\alpha^\eta$  such that the last ordinal  $\beta_\gamma^Y$  in  $p$  played by player I is greater than or equal to  $\gamma$  and  $X_\gamma^Y$  has measure one with respect to the last measure in  $p$ . We then define the  $\mathcal{T}^\eta$ -successors of  $Y$  to be player II’s  $\tau_\alpha^\eta$ -responses to the  $\beta_\gamma^Y$ ’s (which are subsets of the  $X_\gamma^Y$ ’s modulo a bounded set and are therefore pairwise almost disjoint).

For limit stages  $\delta < \lambda$  we apply  $\tau_0$  to the branches of  $\mathcal{T}^\eta \upharpoonright \delta$  to get  $\mathcal{T}_\delta^\eta$ .

We now have to check that the inductive assumptions still hold; let us start with the tree strategy. Assume that we have a partial play  $p$  of length  $2 \cdot \alpha + 1$  of  $\mathcal{G}(\kappa) \upharpoonright \eta$ , i.e. the last move in  $p$  is by player II, consistent with  $\tau_\alpha^\eta$ ; write  $\xi_p$  for player I’s last move in  $p$  and  $Y_p$  for player II’s response to  $\xi_p$ , which is also the last move in  $p$ . We can then pick a  $\zeta < \eta$  such that  $\beta_\zeta^{Y_p} > \xi_p$  by the cofinally many responses property and let  $\tau_{\alpha+1}^\eta(p)$  be player II’s  $\tau_\alpha^\eta$ -response to the partial play leading up to  $\beta_\zeta^{Y_p}$ . After this  $(\alpha + 1)$ ’th round we just set  $\tau_{\alpha+1}^\eta$  to follow  $\tau_0$ . It is clear that  $\tau_{\alpha+1}^\eta$  satisfies the required properties.

Before we move on to checking the remaining inductive assumptions, let us pause to get some intuition about the tree strategies. In the definition of  $\tau_{\alpha+1}^\eta$  above,

---

<sup>8</sup>Two subsets  $X, Y \subseteq \kappa$  are *almost disjoint* if  $|X \cap Y| < \kappa$ .

<sup>9</sup>In particular, we assume that  $\tau_\alpha^\eta$  is defined.

we took a partial play consistent with  $\tau_\alpha^\eta$ , applied  $\tau_0$  for a while, took note of player II's last  $\tau_0$ -response and then included *only that* response in our new  $\tau_{\alpha+1}^\eta$  partial play. This means that to every  $\tau_\alpha^\eta$ -partial play there is an ostensibly much longer  $\tau_0$ -partial play into which  $\tau_\alpha^\eta$  embeds; so we can look at the  $\tau_\alpha^\eta$ -partial plays as being “collapsed”  $\tau_0$ -partial plays.

Given the above tree strategy,  $\mathcal{T}_{\alpha+1}^\eta$  clearly satisfies the cofinally many responses property and the positivity property, simply by construction. For the unique pre-history, let  $Y \in \mathcal{T}_{\alpha+1}^\eta$  and assume it has two distinct immediate  $\mathcal{T}^\eta$ -predecessors  $Z_0, Z_1 \in \mathcal{T}_\alpha^\eta$ . But then  $Y \subseteq Z_0 \cap Z_1$  and  $Y$  is  $I_{Z_0}^{\tau_\alpha^\eta}$ -positive by the positivity assumption, contradicting that  $Z_0$  and  $Z_1$  are almost disjoint by the almost disjointness property. Given the unique pre-history we then also get the almost disjointness property.

*Claim 4.11.*  $\mathcal{T}^\eta \restriction \alpha + 2$  satisfies the hopeless ideal coherence property.

PROOF OF CLAIM. Let  $Y \in \mathcal{T}_{\alpha+1}^\eta$  – we have to show that

$$I_{\langle \rangle}^{\tau_{\alpha+1}^\eta} \cap \mathcal{P}(Y) = I_Y^{\tau_{\alpha+1}^\eta} \cap \mathcal{P}(Y). \quad (1)$$

It is clear that  $I_{\langle \rangle}^{\tau_{\alpha+1}^\eta} \subseteq I_Y^{\tau_{\alpha+1}^\eta}$ , so let  $Z \in I_Y^{\tau_{\alpha+1}^\eta} \cap \mathcal{P}(Y)$  and assume for a contradiction that  $Z$  is  $I_{\langle \rangle}^{\tau_{\alpha+1}^\eta}$ -positive. Letting  $\vec{\alpha}_\xi * \vec{Y}_\xi$  be a play of  $\mathcal{G}(\kappa) \restriction \eta$  consistent with  $\tau_{\alpha+1}^\eta$  such that  $Z$  is in the final measure, the definition of  $\tau_{\alpha+1}^\eta$  yields that  $Y_\alpha \in \mathcal{T}_{\alpha+1}^\eta$ . As  $Z \in I_Y^{\tau_{\alpha+1}^\eta}$  we have to assume that  $Y \neq Y_\alpha$ , so that the almost disjointness property implies that

$$|Y \cap Y_\alpha| < \kappa. \quad (2)$$

By the choice of  $\vec{\alpha}_\xi * \vec{Y}_\xi$  there is some  $\delta \in (\alpha, \lambda)$  such that  $|Y_\delta - Z| < \kappa$ , i.e. that  $Y_\delta$  is a subset of  $Z$  modulo a bounded set, since the  $Y_\alpha$ 's generate the final measure of the play. But then  $Y_\delta \subseteq Y_\alpha$  by the rules of  $\mathcal{G}(\kappa) \restriction \eta$ , and also that  $|Y_\delta - Y| < \kappa$  since  $Z \subseteq Y$ . But this means that  $Y \cap Y_\alpha$  is  $I_Y^{\tau_{\alpha+1}^\eta}$ -positive since  $Y_\delta$  is, contradicting (2). This shows (1).  $\dashv$

This finishes the construction of  $\mathcal{T}_{\alpha+1}^\eta$ . For limit levels  $\delta < \lambda$  we define  $\tau_\delta^\eta$  as simply applying  $\tau_0$  to the branches of  $\mathcal{T}^\eta \restriction \delta$  – showing that the inductive assumptions hold at  $\mathcal{T}_\delta^\eta$  is analogous to the above arguments, so we are now done with the construction of  $\mathcal{T}^\eta$ . Let  $\tau^\eta := \bigcup_{\alpha < \lambda} \tau_\alpha^\eta \restriction {}^{<\alpha}H_{\kappa^+}$  and define<sup>10</sup>  $\mathcal{I}^\eta := I_{\langle \rangle}^{\tau^\eta}$ .

Now note that  $\mathcal{I}^{\eta+1} \subseteq \mathcal{I}^\eta$  and  $\mathcal{T}^\eta \subseteq \mathcal{T}^{\eta+1}$  for every  $\eta < \kappa^+$  – define the ideal  $\mathcal{I} := \bigcap_{\eta < \kappa^+} \mathcal{I}^\eta$  and the tree  $\mathcal{T} := \bigcup_{\eta < \kappa^+} \mathcal{T}^\eta$ . We showed in Claim 4.10 that  $\mathcal{I}$  is  $\kappa$ -complete, normal and  $(\kappa, \kappa)$ -distributive.

We claim that  $\mathcal{T}$  is dense in  $\mathcal{P}(\kappa)/\mathcal{I}$ .<sup>11</sup> Let  $X$  be an  $\mathcal{I}$ -positive set, making it  $\mathcal{I}^\eta$ -positive for some  $\eta < \kappa^+$ , meaning that there is a play  $\vec{\alpha}_\gamma * \tau^\eta$  of  $\mathcal{G}(\kappa) \restriction \eta$  such that  $X$  is in the final measure, which means that  $|Y_\delta - X| < \kappa$  for some large  $\delta < \lambda$  and in particular that  $Y_\delta - X \in \mathcal{I}$ . But  $Y_\delta \in \mathcal{T}^\eta \subseteq \mathcal{T}$  by definition of  $\tau^\eta$ , which shows that  $\mathcal{T}$  is dense.

It remains to show that  $\mathcal{T}$  is  $<\lambda$ -closed. If  $\lambda = \omega$  then this is trivial, so assume that  $\lambda \geq \omega_1$ . Let  $\beta < \lambda$  and let  $\langle Z_\alpha \mid \alpha < \beta \rangle$  be a  $\subseteq$ -decreasing sequence of elements  $Z_\alpha \in \mathcal{T}$ . We can fix some  $\eta < \kappa^+$  such that  $Z_\alpha \in \mathcal{T}^\eta$  for every  $\alpha < \beta$  by regularity of  $\kappa^+$ , and since the  $Z_\alpha$ 's are  $\subseteq$ -decreasing they must also be  $\leq_{\mathcal{T}^\eta}$ -increasing by the hopeless ideal coherence for  $\mathcal{T}^\eta$ .<sup>12</sup>

Let  $\tilde{Z} \in \mathcal{T}^\eta$  be player II's  $\tau^\eta$ -response to the unique partial play of  $\mathcal{G}(\kappa) \restriction \eta$  corresponding to the branch containing the  $Z_\alpha$ 's, and pick  $Z \in \mathcal{T}^\eta$  such that  $|Z - \tilde{Z}| < \kappa$  and  $Z \geq_{\mathcal{T}^\eta} Z_\alpha$  for all  $\alpha < \beta$ , again by the density claim and the hopeless ideal coherence. Then  $Z$  witnesses  $<\lambda$ -closure of  $\mathcal{T}$ .<sup>13</sup> ■

With a bit more work we can from this result then derive the following equivalences.

**COROLLARY 4.12 (N.).** *Let  $\kappa$  be a regular cardinal and  $\lambda \in [\omega_1, \kappa^+]$  be regular. Then the following are equivalent:*

- (i)  $\kappa$  is  $<\lambda$ -closed faintly power-measurable;
- (ii)  $\kappa$  is  $<\lambda$ -closed ideally power-measurable;
- (iii)  $\kappa$  is  $(\kappa, \kappa)$ -distributive  $<\lambda$ -closed faintly measurable;
- (iv)  $\kappa$  is  $(\kappa, \kappa)$ -distributive  $<\lambda$ -closed ideally measurable;

---

<sup>10</sup>Note that the tree strategy property above ensures that the strategies *do* line up, so that  $\tau^\eta$  is a well-defined strategy as well.

<sup>11</sup>This means that given any  $\mathcal{I}$ -positive set  $X$  there is a  $Y \in \mathcal{T}$  such that  $Y - X \in \mathcal{I}$ .

<sup>12</sup>This is the only place in which we are using hopeless ideal coherence.

<sup>13</sup>We are using that  $\lambda$  is regular to get  $Z$ .

(v) *Player II has a winning strategy in  $\mathcal{G}_\lambda(\kappa)$ .*

PROOF. (v)  $\Rightarrow$  (iv) is Theorem 4.9 above<sup>14</sup> and (iv)  $\Rightarrow$  (iii) + (ii), (iii)  $\Rightarrow$  (i) and (ii)  $\Rightarrow$  (i) are trivial, so we show (i)  $\Rightarrow$  (v).

Assume  $\kappa$  is  $<\lambda$ -closed faintly power-measurable, so there is a  $<\lambda$ -closed forcing  $\mathbb{P}$  and a  $V$ -generic  $g \subseteq \mathbb{P}$  such that, in  $V[g]$ , there exists a transitive class  $N$  and a  $\kappa$ -powerset preserving elementary embedding  $\pi: V \rightarrow N$ . Write  $\mu$  for the induced weakly amenable  $V$ -normal  $V$ -measure on  $\kappa$ . Now, back in  $V$ , define a strategy  $\sigma$  for player II in  $G_\lambda(\kappa)$  as follows.

Whenever player I plays some model  $M_\alpha$  then we let player II respond with a filter  $\mu_\alpha$  such that, for some  $p_\alpha \in \mathbb{P}$ ,  $p_\alpha \Vdash \check{\mu}_\alpha = \dot{\mu} \cap \check{M}_\alpha^\top$  – such a filter exists because  $\mu$  is weakly amenable. We require the  $p_\alpha$ 's to be decreasing, which is possible by  $<\lambda$ -closure. Now, all the  $\mu_\alpha$ 's are clearly  $M_\alpha$ -normal  $M_\alpha$ -measures on  $\kappa$ , which makes  $\sigma$  a winning strategy. ■

Note that the above results all relied on  $\lambda$  being uncountable to achieve well-foundedness of the generic ultrapower. If we simply ignore this well-foundedness aspect then we get the following similar equivalence in the  $\lambda = \omega$  case, which then also includes completely ineffable cardinals.

**COROLLARY 4.13 (N).** *Let  $\kappa$  be a regular cardinal. Then the following are equivalent:*<sup>15</sup>

- (i) *There exists a forcing poset  $\mathbb{P}$  such that, in  $V^\mathbb{P}$ , there is a weakly amenable  $V$ -normal  $V$ -measure on  $\kappa$ ;*
- (ii) *There exists a  $(\kappa, \kappa)$ -distributive forcing poset  $\mathbb{P}$  such that, in  $V^\mathbb{P}$ , there is a  $V$ -normal  $V$ -measure on  $\kappa$ ;*
- (iii)  *$\kappa$  carries a normal  $(\kappa, \kappa)$ -distributive ideal;*
- (iv) *Player II has a winning strategy in  $\mathcal{G}_\omega^-(\kappa)$ ;*
- (v)  *$\kappa$  is completely ineffable.*

---

<sup>14</sup>Here well-foundedness of the generic ultrapower is automatic since  $\lambda$  has uncountable cofinality.

<sup>15</sup>Points (i) and (ii) look a lot like the definition of faintly power-measurable and  $(\kappa, \kappa)$ -distributive ideally measurable, but here we are not requiring the ultrapowers to be well-founded, so that would be stretching the definition of being measurable.

PROOF.  $(iv) \Leftrightarrow (v)$  was shown in Theorem 3.30, and  $(iii) \Rightarrow (ii)$  and  $(ii) \Rightarrow (i)$  are trivial.  $(i) \Rightarrow (iv)$  is as  $(i) \Rightarrow (v)$  in Corollary 4.12, and  $(iv) \Rightarrow (iii)$  is Theorem 4.9. ■

As an immediate consequence we then get another ideal-absoluteness result.

**COROLLARY 4.14.** “ $(\kappa, \kappa)$ -distributive  $<\lambda$ -closed” is ideal-absolute for all regular  $\lambda \in [\omega, \kappa^+]$ . ■

We get the following similar results for the Cohen games<sup>16</sup>.

**THEOREM 4.15 (N).** Let  $\kappa$  and  $\lambda \leq \kappa$  be regular infinite cardinals such that  $2^{<\theta} < \kappa$  for every  $\theta < \lambda$ . If player II has a winning strategy in  $\mathcal{C}_\lambda^-(\kappa)$  then  $\kappa$  carries a  $\lambda$ -complete ideal  $\mathcal{I}$  such that  $\mathcal{P}(\kappa)/\mathcal{I}$  is forcing equivalent to  $\text{Add}(\lambda, 1)$ .

PROOF. We follow the proof of Theorem 4.9 closely. Set  $\mathbb{P} := \text{Col}(\lambda, 2^\kappa)$ . Fix a wellordering  $<_{\kappa^+}$  of  $H_{\kappa^+}$  and a  $\mathbb{P}$ -name  $\pi$  for a sequence  $\langle \mathcal{N}_\gamma \mid \gamma < \lambda \rangle \in V^\mathbb{P}$  such that

- $\mathcal{N}_\gamma \in V$  for every  $\gamma < \lambda$ ;
- $\kappa+1 \subseteq \mathcal{N}_\gamma$  and  $|\mathcal{N}_\gamma - H_\kappa|^V < \lambda$  for every  $\gamma < \lambda$ ;
- If  $\delta < \lambda$  is a limit ordinal then  $\mathcal{N}_\delta = \bigcup_{\gamma < \delta} \mathcal{N}_\gamma$ ,  $\mathcal{N}_\delta \prec H_{\kappa^+}$  and it holds that  $\mathcal{N}_\delta \models \text{ZFC}^-$ ;
- $\mathcal{N}_\gamma \cup \{\mathcal{N}_\gamma\} \subseteq \mathcal{N}_\beta$  for all  $\gamma < \beta < \lambda$ ;
- $\mathcal{P}(\kappa)^V \subseteq \bigcup_{\gamma < \lambda} \mathcal{N}_\gamma$ .

Define the auxilliary game  $\mathcal{G}(\kappa)$  as in the proof of Theorem 4.9 but where player I plays ordinals  $\alpha_\eta < \lambda$  and where we use the above  $\mathcal{N}_\gamma$ 's. Here we only need  $<\lambda$ -closure of  $\mathbb{P}$  to get an equivalence between  $\mathcal{G}(\kappa)$  and  $\mathcal{C}_\lambda^-(\kappa)$ , since  $|\mathcal{N}_\gamma - H_\kappa|^V < \lambda$  for all  $\gamma < \lambda$ .

To every limit ordinal  $\eta < \lambda$  we define the restricted auxilliary game  $\mathcal{G}(\kappa) \upharpoonright \eta$  as in the proof of Theorem 4.9, and to every winning strategy  $\tau$  in  $\mathcal{G}(\kappa) \upharpoonright \eta$  and

---

<sup>16</sup>Theorem 4.15 is the reason for naming the  $\mathcal{C}$ -games “Cohen games”.

partial play  $p$  of  $\mathcal{G}(\kappa) \restriction \eta$  consistent with  $\tau$  define the associated **hopeless ideal**

$$I_p^\tau \restriction \eta := \{X \subseteq \kappa \mid \text{For every play } \vec{\alpha}_\gamma * \tau \text{ extending } p \text{ in } \mathcal{G}(\kappa) \restriction \eta, \\ X \text{ is not in the final measure}\}.$$

Now, if  $\kappa$  is measurable then we trivially get the conclusion,<sup>17</sup> so assume  $\kappa$  is not measurable. Then  $\text{sat}(\kappa) \geq \lambda$  since  $2^{<\theta} < \kappa$  for every  $\theta < \lambda$ ,<sup>18</sup> so that we can continue exactly as in the proof of Theorem 4.9 to construct ( $\lambda$ -sized) trees  $\mathcal{T}^\eta$  and winning strategies  $\tau^\eta$  for all limit ordinals  $\eta < \lambda$  such that, setting  $\mathcal{I} := \bigcap_{\eta < \lambda} I_{\langle \rangle}^{\tau^\eta}$  and  $\mathcal{T} := \bigcup_{\eta < \lambda} \mathcal{T}^\eta$ ,  $\mathcal{T}$  is a dense  $<\lambda$ -closed subset of  $\mathcal{P}(\kappa)/\mathcal{I}$  of size  $\lambda$ , so that  $\mathcal{P}(\kappa)/\mathcal{I}$  is forcing equivalent to  $\text{Add}(\lambda, 1)$ . ■

**COROLLARY 4.16 (N).** *Let  $\kappa$  and  $\lambda \in [\omega_1, \kappa]$  be regular such that  $2^{<\theta} < \kappa$  for every  $\theta < \lambda$ . Then the following are equivalent:*

- (i)  $\kappa$  is  $<\lambda$ -closed faintly measurable;
- (ii)  $\kappa$  is  $<\lambda$ -closed ideally measurable;
- (iii)  $\kappa$  is  $<\lambda$ -closed  $\lambda$ -sized faintly measurable;
- (iv)  $\kappa$  is  $<\lambda$ -closed  $\lambda$ -sized ideally measurable;
- (v) Player II has a winning strategy in  $\mathcal{C}_\lambda(\kappa)$ .

**PROOF.**  $(iv) \Rightarrow (iii) + (ii)$ ,  $(ii) \Rightarrow (i)$  and  $(iii) \Rightarrow (i)$  all trivial, and  $(i) \Rightarrow (v)$  is like  $(i) \Rightarrow (v)$  in Corollary 4.12, and  $(v) \Rightarrow (iv)$  is Theorem 4.15. ■

Again, if we ignore well-foundedness then we get the same equivalence in the  $\lambda = \omega$  case:

**COROLLARY 4.17 (N).** *Let  $\kappa$  be regular infinite. Then the following facts hold:*

- (i) Player II has a winning strategy in  $\mathcal{C}_\omega^-(\kappa)$ ; and
- (ii)  $\kappa$  carries an ideal  $I$  such that  $\mathcal{P}(\kappa)/I$  is forcing equivalent to  $\text{Add}(\omega, 1)$ .

**PROOF.** Player II has a winning strategy in  $\mathcal{C}_\omega^-(\kappa)$  as we are simply measuring finitely many sets without any demand for well-foundedness, showing (i). Since

---

<sup>17</sup>Take  $\mathcal{I}(\text{Add}(\lambda, 1), \mu)$  for  $\mu$  the measure on  $\kappa$ .

<sup>18</sup>See Proposition 16.4 in [Kanamori, 2008].

$2^{<n} < \kappa$  for all  $n < \omega$  as  $\kappa$  is infinite, Theorem 4.15 then implies (ii). ■

**COROLLARY 4.18** (N.). *The property “ $<\lambda$ -closed  $\lambda$ -sized” is ideal-absolute for all regular  $\lambda \in [\omega, \kappa]$  such that  $2^{<\theta} < \kappa$  for all  $\theta < \kappa$ .* ■

With this corollary, our journey has come to an end. An ending, which is nothing but an oxymoron in one of these perennial mathematical journeys, so instead consider the following final chapter my baton to you, dear reader.

*Natten bøjer sig i vækst;  
Og dagene vasker dit ansigt.  
Du træder gennem sønnen;  
Og åbner en dør til solen.  
Dér, ikke i dit eget lys;  
Bærer du kroppen;  
Strømmet igennem af blod.  
Dér er du menneske nu;  
Og du går for at finde din tid.

## 5 | FURTHER QUESTIONS

Here we record many open questions related to the content of the preceeding chapters, broadly separated by topic.

### 5.1 RELATIONS BETWEEN VIRTUALS

The analysis in Chapter 2 showed several implication and separation results between the virtual large cardinals. A few of these relations remain open, however.

**QUESTION 5.1.** Are virtually  $\theta$ -strong cardinals, virtually  $\theta$ -supercompact cardinals and virtually  $\theta$ -Magidor-supercompact cardinals all equivalent, for any uncountable regular cardinal  $\theta$ ?

**QUESTION 5.2.** Let  $\theta$  be an uncountable cardinal.

- (i) Is every virtually  $\theta$ -measurable cardinal also virtually  $\theta$ -prestrong? What if we assume  $V = L[\mu]$  or  $V = K$ , with  $K$  being the core model below a Woodin cardinal?
- (ii) Is every virtually  $\theta$ -strong cardinal virtually  $\theta$ -supercompact? Are they equiconsistent?

### 5.2 BERKELEYS

Question 1.7 in [Wilson, 2018] asks whether the existence of a non- $\Sigma_2$ -reflecting *weakly remarkable* cardinal always implies the existence of an  $\omega$ -Erdős cardinal. Here a weakly remarkable cardinal is a rewording of a virtually prestrong cardinal, and Lemmata 2.5 and 2.8 in the same paper also shows that being  $\omega$ -Erdős is equivalent to being virtually club Berkeley and that the least such is also the least virtually Berkeley.<sup>1</sup>

---

<sup>1</sup>Note that this also shows that virtually club Berkeley cardinals and virtually Berkeley cardinals are equiconsistent, which is an open question in the non-virtual context.

Furthermore, they also showed that a non- $\Sigma_2$ -reflecting virtually prestrong cardinal is equivalent to a virtually prestrong cardinal which is not virtually strong. We can therefore reformulate their question to the following equivalent question.

**QUESTION 5.3** (Wilson). If there exists a virtually prestrong cardinal which is not virtually strong, is there then a virtually Berkeley cardinal?

[Wilson, 2018] showed that their question has a positive answer in  $L$ , which in particular shows that they are equiconsistent. Applying our Theorem 2.10 we can ask the following related question, where a positive answer to that question would imply a positive answer to Wilson's question.

**QUESTION 5.4.** If there exists a cardinal  $\kappa$  which is virtually  $(\theta, \omega)$ -superstrong for arbitrarily large cardinals  $\theta > \kappa$ , is there then a virtually Berkeley cardinal?

Theorem 2.43 from Chapter 2 at least gives a partially positive result, noting that the assumption by definition implies that  $\text{On}$  is virtually pre-Woodin but not virtually Woodin.

**COROLLARY 5.5** (N.). *If there exists a virtually  $A$ -prestrong cardinal for every class  $A$  and there are no virtually strong cardinals, then there exists a virtually Berkeley cardinal.* ■

The assumption that there is a virtually  $A$ -prestrong cardinal for every class  $A$  in the above corollary may seem a bit strong, but Theorem 2.43 shows that this is necessary, which might lead one to think that the question could have a negative answer.

### 5.3 INDESTRUCTIBILITY

Our original goal concerning indestructibility was to see what indestructibility properties the faintly supercompacts have, whether any analogy with the supercompact cardinals holds. This still remains open.

**QUESTION 5.6.** Do faintly supercompact cardinals have indestructibility properties? For instance, if  $\kappa$  is faintly supercompact, does it remain supercompact after forcing with  $\text{Add}(\kappa, 1)$ ?

We proved several indestructibility properties of the ostensibly stronger notion of *generically setwise supercompacts*, and several questions then arise concerning the nature of these cardinals.

**QUESTION 5.7.** What is the consistency strength of the generically setwise supercompact cardinals? The best upper bound is a virtually extendible, as given by Usuba’s Theorem 2.56, and a lower bound is the trivial faintly supercompact one. What if we require the cardinal to be inaccessible?

**QUESTION 5.8.** Is it consistent to have a faintly supercompact cardinal which is not generically setwise supercompact?

**QUESTION 5.9.** Assume there exists no inner model with a Woodin cardinal. Can there then exist generically setwise supercompact cardinals in  $K$ ?

## 5.4 GAMES AND SMALL EMBEDDINGS

Our results in Chapter 3 provide answers to the following questions, which were posed in [Holy and Schlicht, 2018].

- (i) If  $\gamma$  is an uncountable cardinal and the challenger does not have a winning strategy in the game  $\mathcal{G}_\gamma^\theta(\kappa)$ , does it follow that the judge has one?
- (ii) If  $\omega \leq \alpha \leq \kappa$ , are  $\alpha$ -Ramsey cardinals downwards absolute to the Dodd-Jensen core model?
- (iii) Does 2-iterability imply  $\omega$ -Ramseyness, or conversely?
- (iv) Does  $\kappa$  having the strategic  $\kappa$ -filter property have the consistency strength of a measurable cardinal?

Here the “challenger” is player I and the “judge” is player II, so this is asking if every  $\gamma$ -Ramsey is strategic  $\gamma$ -Ramsey, when  $\gamma$  is an uncountable cardinal. Theorem 3.65 therefore gives a negative answer to (i) for all uncountable ordinals  $\gamma$ . Theorem 3.51 and Corollary 3.52 answer (ii) positively, for  $\alpha$ -Ramseys with  $\alpha$  having uncountable

cofinality, and for  $<\alpha$ -Ramseys when  $\alpha$  is a limit of limit ordinals. Note that (ii) in the  $\alpha = \omega$  case was answered positively in [Holy and Schlicht, 2018].

As for (iii), it is mentioned in [Holy and Schlicht, 2018] that Gitman has showed that  $\omega$ -Ramseys are not in general 2-iterable by showing that 2-iterables have strictly stronger consistency strength than the  $\omega$ -Ramseys, which also follows from Theorem 3.36 and Theorem 4.8 in [Gitman and Welch, 2011]. Corollary 3.22 shows that  $\omega$ -Ramsey cardinals are  $\Delta_0^2$ -indescribable, and as 2-iterables are (at least)  $\Pi_3^1$ -definable it holds that any 2-iterable  $\omega$ -Ramsey cardinal is a limit of 2-iterables, so that in general 2-iterables cannot be  $\omega$ -Ramsey either, answering (iii) in the negative. Lastly, Theorem 3.47 gives a positive answer to (iv).

We conjecture the following two questions to be true. The first is a direct analogue to Theorem 3.31, and the latter is a suspected analogy between the genuine  $n$ -Ramsey cardinals and the weakly ineffable cardinals.

**QUESTION 5.10.** If  $\kappa$  is faintly  $\theta$ -power-measurable, does player II then have a winning strategy in  $\mathcal{G}_\omega^\theta(\kappa)$ ?

**QUESTION 5.11.** Are genuine  $n$ -Ramsey cardinals limits of  $n$ -Ramsey cardinals? We conjecture this to be true, in analogy with the weakly ineffables being limits of weakly compacts. Since “weakly ineffable =  $\Pi_1^1$ -indescribability + subtlety”, this might involve some notion of “ $n$ -iterated subtlety”. The difference here is that  $n$ -Ramseys cannot be *equivalent* to  $\Pi_{2n+1}^1$ -indescribables for consistency reasons, so there is some work to be done.

We showed in Theorem 3.30, see also Corollary 4.13 that completely ineffable cardinals could be characterised in terms of player II having a winning strategy in  $\mathcal{G}_\omega^-(\kappa)$ . This lends itself to the following question.

**QUESTION 5.12.** Are there higher analogues of ineffability which are equivalent to player II having a winning strategy in  $\mathcal{G}_\alpha^-(\kappa)$  for  $\alpha > \omega$ ?

## 5.5 IDEAL ABSOLUTENESS

One can ask of any poset property whether it is ideal-absolute, but we choose to only highlight one particular property here. We saw in Corollary 4.12 that  $<\lambda$ -closed

faintly power-measurables “corresponds to”  $(\kappa, \kappa)$ -distributive  $<\lambda$ -closed forcings, and in Corollary 4.13 that completely ineffable cardinals “corresponds to”  $(\kappa, \kappa)$ -distributive forcings. In an attempt to find the forcing that corresponds to the faintly power-measurables, we arrive at the following question.

**QUESTION 5.13.** For  $\kappa$  a regular cardinal, are the following equivalent?

- (i)  $\kappa$  is faintly power-measurable;
- (ii)  $\kappa$  is ideally power-measurable;
- (iii)  $\kappa$  is  $(\kappa, \kappa)$ -distributive  $\omega$ -distributive faintly measurable;
- (iv)  $\kappa$  is  $(\kappa, \kappa)$ -distributive  $\omega$ -distributive ideally measurable;
- (v) Player II has a winning strategy in  $\mathcal{G}_\omega(\kappa)$ .
